The Route World:
A Golden-Reasoning Hypothesis of Biospheric Natural History

Ajax Benander*

September 2026 — Working Draft, rev. 5

Abstract

This paper states a hypothesis about the record of natural history and develops what would follow from it. The hypothesis, the Route World, is that the record is drawn under the survivorship-conditioned law of a specific target, the Golden Point, the state past which a biosphere's external hazard is driven to zero; the theorem that such a draw produces realized attributes according with its target is proved in a companion and imported, and this paper's claim is the between-model one that the theorem does not license, that our record is drawn so. The claim in one sentence: under the stated counterfactual-weight and target-requirement assumptions, the record of natural history yields a Bayes factor favoring conditioning on the biosphere's indefinite survival over conditioning on the existence of observers, prospectively estimating that factor is the empirical test, and every consequence drawn from the hypothesis is carried at the grade of a hypothesis with stated tests. This section is a protocol template and not yet a fully specified test: named attributes, likelihoods under both laws, dates, thresholds and scoring rules are still to be supplied, the Bayes-factor identity supplies neither likelihood, and the claim that the record already supplies strong evidence is conditional on the strongest empirical assumptions. Four things are developed. The target is constructed rather than stipulated: the Departure Point as the least fixed point of an implication cascade, and the Continuity Principle that makes one target bear on a Mesozoic mammal and on a launch vehicle, without which no conditioning could run across the record. The two arguments at the record's two grains, human history and natural history, are stated as model comparisons, with the human-history leg's flukes read as within-model diagnostics and the natural-history leg's counterfactual weight bounded and calibrated against once-only attributes. The retrocausal instrument is stated as an instance of the imported theorem and of the imported scoping of one's own Aethus for inhabitability; the finale paradox it dissolves and the investment reading it licenses are developed separately. And the Route World's discriminating quantities are named as the information flux and a provisioning base rate, with the flagship test stated prospectively: a predeclared attribute family, a baseline, a target relation, a stopping rule, and a multiplicity budget, declared today and scored on what follows. The retrospective cases are labeled exploratory. The strong reading is stated once in the framework's primitives, as the Golden Axiom: that it is a parent Aethus to one's Aethus that the universe is conditioned on one's biosphere's surviving through every proper time. The author's argument that it holds, the Paradox of Departures, is recorded at its grade in a general form, which caps the weight of a departure short of the Golden Point by the record's own Cosmic weight, and an

*Email: akb9408@rit.edu. This paper states and develops a hypothesis; the theorem it rests on, that a record drawn under a law conditioned on a future target has realized attributes that accord with the target, is proved in a companion [1], and the survivorship model in another [2]. Both are cited and restated, neither presupposed, and the hypothesis is carried throughout at a hypothesis's grade. Drafting collaboration: Anthropic Claude (Opus 4.x, Fable 5), under the author's direction.

external one, whose bi-distribution bounds a departure within one's lifetime by the external channel below one in $e\tau_{\oplus}/\ell$, about 10^8, under every hazard rate. What is refused is stated once: no agent, no certification, no occupant.

1 Introduction

A companion proves a theorem about records and targets: if the realized member of a binary partition of the past is drawn under a law conditioned on a future event, then the realized member typically accords with that event, to within an exceedance the draw prices, and the statement is indifferent to whether the event lies in the past or the future [1]. The theorem is a conditional. It says what a record looks like under a future-targeted draw. It does not say that any record is drawn so, and it is careful to say that it does not. This paper takes the step the theorem declines, and takes it as a hypothesis. It proposes that the record of natural history is drawn under conditioning on a specific future target, the indefinite survival of the biosphere, and it asks what follows, how the proposal could be wrong, and what would show it.

The claim, in one sentence. Under the stated counterfactual-weight and target-requirement assumptions, the record of natural history yields a Bayes factor favoring conditioning on the biosphere's indefinite survival over conditioning on the existence of observers; prospectively estimating that factor, with both probabilities fixed independently of the record they are scored on, is the empirical test; and every consequence drawn from the hypothesis carries a stated test.

What is imported. The theorem companion supplies future-targeted accordance, its prior-bound corollary, the conjunction form under submultiplicativity, the multiplicity guard, the horizon-indexed specialization to survival targets, the identification of the Bayes factor with the Doob density, the information flux, and the limit on certification [1], together with the scoping of an Aethus for inhabitability, of which future-targeted accordance is the instance at one's own Aethus. The technoanatomy companion supplies the emergence theorem, that survival conditioning selects any fractional lowering of the total hazard however rare the structure that buys it [3]. The survivorship companion supplies the model and its Q-process [2]. The Nexic companion supplies the Accordance Principle at a general target, the Imperfection Magnitude Drop, and the hyperblock construction that fixes what counts as a nameable variation of ourselves [4]. Each is restated in Section 3 at its grade.

What is new. The target, constructed from the record's side (Section 4). The hypothesis and its two arguments as model comparisons (Section 5). The natural-history leg's counterfactual weight, bounded from below by the single-flip sum (Section 6). The Route World's discriminators and its prospective test (Sections 7 and 10). And the fences (Section 9). The strong reading is stated once in the framework's primitives as the Golden Axiom (Section 7.1), and the author's argument that it holds, the Paradox of Departures, is recorded in its general and external forms (Section 8). The retrocausal instrument's phenomenology, the finale paradox and the investment reading, is developed separately and is not part of the hypothesis stated here.

Position in the branch. The Golden branch is four papers in a strict order of import, and this paper is its terminal synthesis. The survivorship companion [2] is the root and owns the stochastic dynamics and the conditioned path laws; the theorem companion [1] owns the general result that a record drawn under a target-conditioned law has realized attributes according with the target, and the model-comparison and multiplicity machinery, and its core theorem depends on nothing Golden; the technoanatomy companion [3] owns the mechanism, the prerequisite schedule through which a lineage under survivorship conditioning is read as pushed, and works

with the survivorship companion's generic viability target without assuming anything stated here. This paper imports all three and owns the hypothesis that one particular target, long-run biospheric survival, explains our record, together with its tests; it cites the technoanatomy companion as a possible mechanism, and no upstream paper cites this one, so the citation graph runs the same way as the logic.

What is refused. No agent behind the conditioning. No certification of the favorable side, which the imported theorem forbids at any finite horizon. No occupant of the target's arrival. And no inference from the theorem to the hypothesis: the theorem is within-model, the hypothesis is between-model, and the two are never run together.

Grades. [P] proved here or in a companion; [S] scaling-level or structural, argued without proof; [Φ] a stipulative commitment stated as such; [O] open, with its specification. The hypothesis itself is [S] throughout and is never upgraded by use.

2 Vocabulary

- **Departure Point.** The irreversible loss of a biosphere's future, constructed as the least fixed point of an implication cascade.
- **Golden Point.** Its complement; the state past which the external hazard is driven to zero; the target.
- **Aethus.** An observer-relative information state: stated attributes, the unstated blank [5].
- **Cosmic Nexus / Golden Nexus.** The occurrence-frequency weighting of attributes, and the same weighting under the target.
- **Accordance.** The imported theorem: under a target-conditioned draw, a realized attribute accords with the target.
- **Past-Alignment.** The hypothesis that the record is drawn under the Golden target; local alignment is the tested form, strong alignment the global one.
- **Fluke.** A route-deleting realized attribute of small prior.
- **Stockpile.** A predeclared, submultiplicative family of flukes, read as one attribute.
- **Task-object.** The individuation by functional role that lets a capacity register as missing in a history where it does not occur.
- **The ceiling.** No event of bounded duration perfectly separates the conditioned law from the unconditioned one.
- **Information flux.** The rate of the relative entropy between the two laws; the Route World's discriminating statistic.
- **Route World.** The hypothesis: the record as the past-cone restriction of the survivorship-conditioned law; in its strong reading, the world in which the Golden Axiom holds.
- **Golden Aethus; Golden Axiom.** The Aethus $\mathfrak{G}$ stating that one's biosphere survives through every proper time, all else blank; and the axiom that it is a parent Aethus of one's own, $H^* \sqsubseteq \mathfrak{G}$, the Strong hypothesis in the framework's primitives.

- **Departing Aethus; Paradox of Departures.** An Aethus in which one's biosphere departs short of the Golden Point; and the author's argument by contradiction that one does not come to occupy one, and so that the Golden Axiom holds.
- **Bi-distribution.** The joint law of the external form's two axes, lateness and window, under every external hazard rate at once.
- **Inhabitability.** The weight an Aethus one might occupy gives one's realized present; scoping weights the Aethus by it.
- **Emergence theorem.** Survival conditioning selects any fractional lowering of the total hazard, however rare the structure that buys it.

3 Imported results

Definition 3.1 (Aethus, the draw, and the general Accordance Principle; from [4])**.** An Aethus is a set of stated attributes with the unstated blank. The draw is the postulate that at each open attribute the realized member is distributed by the parent-conditional weights of the law in force. The Accordance Principle, stated at a general conditioning target in a tense-free containment chain, bounds the ratio of the target's conditional probabilities across a realized attribute and its complement by the attribute's odds, with κ-fold exceedances confined to probability $1/(1+\kappa)$ for $\kappa > 1$.

Theorem 3.2 (Future-targeted accordance; **[P]** in [1])**.** *Let $\{A, A'\}$ be a binary partition of the past and B a target with $\mathbb{P}(B) > 0$. If the realized member A^* is drawn under $\mathbb{P}_B = \mathbb{P}(\cdot \mid B)$, then for every $\kappa > 1$, $\mathbb{P}_B[\mathbb{P}(B \mid A^{*\prime})/\mathbb{P}(B \mid A^*) \geq \kappa\, \mathbb{P}(A^*)/\mathbb{P}(A^{*\prime})] \leq 1/(1+\kappa)$. For a survival target in the critical regime the target is the horizon family $\{T > t\}$ and the Q-process its limit. The theorem is within-model; the inference from accordance to the draw is between-model and is the Bayes factor $Q(E)/\mathbb{P}(E)$, which at finite information is the Doob density.*

Definition 3.3 (Imperfection Magnitude Drop, and the hyperblock; from [4])**.** An Imperfection Magnitude Drop is an alternative natural history whose joint probability with the target is drastically minute but nonzero, reached as a targeted perturbation of one's own Aethus. The biological hyperblock cosmos is the canvas on which any planet is representable as an alternate history of the Earth by varying a stated set of its attributes; it fixes the class of nameable variations of ourselves.

Definition 3.4 (The model, and the Golden Point in it; from [2])**.** The total hazard is $h_t = B_t \varsigma_b(x_t) + \Gamma e^{-\rho x_t}$, an external background muffled by accumulated capacity plus an internal term the same capacity feeds or starves by the sign of ρ; Departure is the killing time, viability the event that the total hazard ever accrued stays finite, and the Golden Point the state past which the external channel is driven to zero and viability obtains.

Theorem 3.5 (Two conditions for viability; **[P]** in [2])**.** *Viability is the indicator of $\rho > 0$ times a piecewise driver-viability functional; the two factors are logically distinct necessary conditions, the first a sign and the second silent on it.*

Theorem 3.6 (The ceiling; **[P]** in [2, 1])**.** *In the critical regime the survivorship-conditioned law is locally absolutely continuous with respect to the unconditioned law on survivors and globally singular; no event of bounded duration perfectly separates the two, so certification of which law*

a record is under is unavailable to any finite sample, while statistical discrimination with error remains possible and is measured by the Bayes factor.

Definition 3.7 (Scoping an Aethus for inhabitability; [Φ] in [1], the author's procedure)**.** Beside its usual application, to an Aethus in which the realized attribute is already known to be actual, the Accordance Principle scopes an Aethus one has not been shown to occupy. Let X be such an Aethus, A^* one's realized present and $A^{*\prime}$ its canonical complement, and suppose X one's own. The *inhabitability*, or admissibility, of X is the weight X gives one's realized present, weights taken under the Cosmic Nexus,

$$\iota(X) \;:=\; \mathbb{P}(A^* \mid X) \;=\; \frac{1}{1+\kappa_X}, \tag{1}$$

with κ_X the exceedance at which occupying X would place the present. To scope X is to weight $\neg X$ with the weight of failing the bound on the supposition of X, $1-\iota(X) = \kappa_X/(1+\kappa_X)$, and X with what remains: $\mathrm{cr}(X) \lesssim \iota(X)$. With c one's confidence in the principle's application and $\pi_0(X)$ the weight X would carry without it, the scoped credence is at most the linear combination $c\,\iota(X) + (1-c)\,\pi_0(X)$. Future-targeted accordance is the scoping's instance at one's own Aethus: pin an attribute B of one's future cone, take one's own Aethus conditioned on the pin, and scope it, its inhabitability $\mathbb{P}(A^* \mid B)$ being the weight Theorem 3.2 prices as an exceedance. Running the pin over the attributes that might occur in one's future cone scopes the admissibility of one's own Aethus under each, each pin predicted, in the author's phrase, with the confidence administered by its non-contradictory weight. Across competing pins the confidences are the inhabitabilities weighted by the pins' prior weights and normalized, not the inhabitabilities themselves, which are likelihoods and need not sum to one; the cap $\mathrm{cr} \lesssim \iota$ is that rule's reading for a pin not favored in advance.

Theorem 3.8 (Emergence: survival conditioning selects any fractional drop in the total hazard; **[P]** in [3] given its hypotheses, the author's theorem)**.** *Divide the histories of one's biosphere into a Golden class G, of prior weight $\alpha \in (0,1)$, the cumulative probability of the exotic structure the Golden Point requires, and a non-Golden class N, of weight $1-\alpha$. Let the two classes' total hazards, the external, internal and schedule channels together, be realized on one probability space, the two classes facing one universe, with cumulative hazards Λ_G and Λ_N and survival functions $S_C(t) = \mathbb{E}\big[e^{-\Lambda_C(t)}\big]$, and suppose that the cumulative gap grows at least linearly, for some $\Delta > 0$ and $K < \infty$:*

$$\Lambda_N(t) - \Lambda_G(t) \;\geq\; \Delta t - K \qquad \text{for all } t \geq 0, \text{ almost surely.} \tag{2}$$

This holds in particular when the Golden Point lowers the center about which the total hazard fluctuates by a fraction $\delta \in (0,1]$, its fluctuations carried along, so that $\Lambda_G \leq (1-\delta)\Lambda_N + K$ with K what the climb costs before the drop takes hold, and the non-Golden hazard has a floor $h_N \geq h_{\min} > 0$; then $\Delta = \delta h_{\min}$. Then the odds of the non-Golden class against the Golden, given survival to η, satisfy

$$O(\eta) \;:=\; \frac{\mathbb{P}(N \mid T > \eta)}{\mathbb{P}(G \mid T > \eta)} \;\leq\; \frac{1-\alpha}{\alpha}\, e^{K - \Delta\eta}, \tag{3}$$

with equality for constant hazards differing by Δ and $K = 0$; for every $\beta > 0$, $O(\eta) < \beta$ at every $\eta > \eta_*$, where

$$\eta_* \;=\; \frac{1}{\Delta}\Big[\log\frac{1-\alpha}{\alpha} + \log\frac{1}{\beta} + K\Big], \tag{4}$$

finite for every $\alpha > 0$; and $\mathbb{P}(G \mid T > \eta) \to 1$ as $\eta \to \infty$. The proof is a line: (2) gives $e^{-\Lambda_N(t)} \le e^{K-\Delta t} e^{-\Lambda_G(t)}$ on every path, so $S_N \le e^{K-\Delta t} S_G$, and Bayes gives the odds.

In the model of Definition 3.4 both hypotheses are supplied. The floor is the technoanatomy companion's gating result: an incomplete schedule leaves the biosphere at bare background with the internal channel at its full coefficient, so the non-Golden hazard is at least Γ; without a floor the non-Golden class could itself be viable and a fractional drop would leave the odds at a positive limit. The coupling is the model's multiplicative fluctuation: a completed biosphere holding credit $x \ge x_* > 0$ has $h^{\mathrm{tot}} \le (1-\delta)(B_t+\Gamma)$ along the same background path, with $1-\delta = \max\{\varsigma_b(x_*), e^{-\rho x_*}\}$, and the schedule channel, which completion closes, only widens the drop. A drop in the mean alone would not do, since a hazard that fluctuates more widely can outsurvive a lower and steadier one. The companion's survival-time threshold, $T_* \approx \log(1/p)/(B+\Gamma)$ for a climb of probability p whose class thereafter decays only polynomially, is to leading order the case of a drop in the whole exponential rate [3].

Definition 3.9 (Task-object; from the Aethic companion [5])**.** A task-object is individuated by the task it performs in a history rather than by its material identity, so that a capacity is comparable across histories in which it does and does not occur; perturbation arguments compare a Task-Earth and a task-lineage, not an Earth and a lineage.

4 The target: the Departure Point, the Golden Point, and continuity

4.1 Choosing the target: continuity and non-privilege

Before the argument for Golden-conditioning, a prior question: why the Golden Point rather than some more familiar target? "Technologically advanced civilization" is the obvious candidate and is the wrong one, for two reasons that compound. It is not well-defined. Any threshold one names, writing, metallurgy, industry, spaceflight, is a stipulation, and the arbitrariness is not cosmetic: every rarity verdict issued relative to such a target inherits it.

And it is *discontinuous with natural history.* A conditioning target must be applicable across the whole record if the record is to be read as one object. "Civilization" applies to the last few millennia and to nothing before, so a framework built on it cannot run a single conditioning across both the end-Cretaceous impact and the Industrial Revolution. It must instead splice two analyses at a joint it has no principled way to locate.

Definition 4.1 (Departure Point)**.** The *Departure Point* is the event past which *every* continuation fails to advance — the first moment at which all scenarios lead to a failure to advance past that point. The modal quantifier is the definition and not an embellishment of it: what is being named is the closure of possibility, not the observation of non-progress. *This is what makes it the dual of the Golden Point.* That was defined as the point past which a biosphere is too capable at self preservation to regress past it — which, stated with the quantifiers exposed, is the point past which *some* available course has *every* continuation avoiding foreclosure. The asymmetry between the two is deliberate: departure is $\forall\exists$ — every course admits a foreclosing continuation — and Goldenness is $\exists\forall$ — some course admits none.

Two $\forall$-statements could not be complements of one another; $\exists\forall$ and $\forall\exists$ can be, and §4.1.1 shows that these two are, by exhibiting them as the complementary fixed points of De Morgan-dual operators. The quantifier asymmetry is therefore not a wrinkle in the duality but its

mechanism. The pair is exhaustive on definite states, and an Aethus carries weight across both. §4.1.4 makes that precise, since it is best stated once the grading is in hand. The reading this forces bears stating, since a looser gloss would lose it. Goldenness is not the guarantee that nothing can go wrong; it is the possession of a *course* along which nothing does, whatever the environment answers. It is a claim about available strategy, not about the absence of hazard — which is why a Golden biosphere still faces a universe that would destroy it and is Golden anyway.

Both are *points* for the same reason: irreversibility. A state one may still leave is not a point but a phase, and neither concept is about phases. Two consequences of stating it this way. *Biological death is a mechanism, not the definition.* Death is one way a trajectory is foreclosed, and it happens to be the most visible one; irreversible loss of the capacity to advance is another, and the definition is indifferent between them. What is extracted is the *phenomenology of foreclosure*, taken apart from the particular mechanism of biosphere-death in which it is most legible — and once extracted it applies wherever there is a trajectory to foreclose, which is why the notion carries across the scales Principle 1 requires.

Non-advancement alone does not suffice. A biosphere that fails to progress for an age has not thereby reached its Departure Point; it has had a lull, and a lull is reversible. Only when no continuation remains that advances has the point been passed. This is the distinction that the phrase "failure to advance" elides and that the quantifier restores. Two consequences for how the model of Section 3 should be read. The hazard h_t^{tot} of the survivorship companion [2] is the hazard *of foreclosure*, not of death; the muffling exponent x is accumulated against that; and every Imperfection Magnitude Drop is a movement toward it. And the analytic form of the modal claim is *pathwise* divergence, $\Lambda_\infty = \infty$ along every continuation, which the trapped regime satisfies outright (the survivorship companion [2](i)), of which $\mathbb{P}(\Lambda_\infty < \infty) = 0$ is the measure shadow; the two come apart exactly where the broader Golden program, set aside here separates them, since the critical regime carries the shadow while advancing continuations survive at measure zero. This is why the trapped regime of the survivorship companion [2](iii) has departed: not because a biosphere halting at x_* has stopped, but because with $\rho < 0$ the viability probability is identically zero, so no continuation available to it advances. Halting is not the departure; having nowhere left to go is.

The term is used rather than "extinction" deliberately, and the reason is the same one that governs the choice of the Golden Point itself. "Extinction" is a biological category, applying to taxa and carrying the vocabulary of one discipline; the Departure Point must apply at every scale the record contains, to a Mesozoic lineage as readily as to a biosphere tomorrow, and must name an event in the Aethic block universe rather than a fact about organisms. It is therefore defined at the same primitive level as the Golden Point, which is what allows Principle 1 to be stated at all.

Internal and external. The Departure Point divides by the locus of its cause. An *internal* Departure Point is brought about by factors within the biosphere's own homeworld; an *external* one is inflicted from outside, and is roughly constant in magnitude over long timescales because the cosmos is roughly constant in makeup. That division is the ontological origin of the two channels of the survivorship companion [2]: the crest channel carries the external hazard and is bounded, the trough channel carries the internal and is not. Technoanatomy (the survivorship companion [2]) is then the statement of how the second responds to capacity acquired against the first.[1]

[1] *Provenance.* The Departure Point, its internal/external division, the constancy of the external threat, and

4.1.1 The implication cascade: departure as a least fixed point

The construction imports the companion's fixed-point result rather than re-deriving it, and reads the proper-child relation $\leq$, the order of the Aethic tree, as the companion reads it, transitively and with its comparative weight condition, $B \leq A$ when B is a component of A whose coefficient is not measure-zero relative to the rest; nothing below depends on generation counts or on finite branching. The passage from the model's verdict to the modal set is a bridge, not an identity: $\Lambda_\infty = \infty$ gives almost-sure eventual Cox killing, while membership in the doom set μG means every admissible continuation is doomed, and the two coincide only under the identification of zero-weight continuations with absent ones, which the framework adopts and states here rather than passing from $\mathbb{P}(T = \infty) = 0$ to $A \in \mu G$ without it.

Definition 4.1 carries a recursion that is worth making explicit, because it is already available in the companion framework in finished form and because it changes what the model's hazard is a hazard *of*. The internal and external hazards of the survivorship companion [2] *imply* departure; they are not exhaustive of it. A biosphere may reach a configuration from which no route avoids those hazards, and by the modal definition that configuration *is* a Departure Point, attained before either hazard has fired. The statement "no matter what you do, you reach a Departure Point" is itself a Departure Point — and since that statement can again be true one step earlier, the implication propagates.

Remark 4.2 (This is the third postulate's operator, imported). The companion's third postulate supplies exactly this recursion [5], and its result is imported as stated there. Over Aethae ordered by the proper-child relation $\leq$, the subrelation of containment $\sqsubseteq$ consisting of the visible terms of decompositions, with Base collecting the non-recursive modes, the safety operator and its dual are

$$F(Y) = \big\{A \notin \text{Base} : \ \exists B \leq A,\ \forall C \leq B,\ C \in Y\big\},$$
$$G(X) = \text{Base} \cup \big\{A : \ \forall B \leq A,\ \exists C \leq B,\ C \in X\big\},$$

both monotone, so that by Knaster–Tarski the greatest fixed point νF and the least fixed point μG exist for arbitrary branching and are complements of one another; the companion's seeded convention fixes Base, and under it $\mathcal{D} = \mu G = G(\text{Base})$ closes. Generation counts, finite branching, and closure ordinals play no role in the imported statement and none here.

Read Base as departure by internal or external hazard — departure-sufficient occurrences in the sense of Definition 3.4, with nothing about death presupposed. Then G is the doom operator in the sense above, every route has a doomed continuation, and the Departure Point is

$$\mathcal{D} \ = \ \mu G \ \supsetneq \ \text{Base}. \tag{5}$$

Three consequences, each already carried by the companion's machinery rather than assumed here.

The implication is one-directional by design. The companion states the third postulate as an implication and not a biconditional, which is precisely the containment in (5): the hazards

the observation that a biosphere may come to draw energy out of itself are all set out in our *Golden Science* of August 2022 [6], some years before the present formalism and before the drafting collaboration. That document also states the Golden Point as the point past which a biosphere cannot regress, derives a positive immortality probability from an exponentially decaying hazard, argues for "biosphere" over "civilization" as the unit, and names the Trace Connection as an open problem — which §5.1 is the attempt to close. The formalism here should be read as supplying machinery for commitments already made there, not as generating them.

suffice for departure and are not necessary to it. *The Golden Point is an event horizon in a precise sense.* It is the state past which the capacity to trigger departure is closed off, which is νF's $\exists\forall$ said in the other direction, and the Departure Point is its dual, the state at which every remaining possibility retains that capacity; the parallel is recorded rather than used.

The Golden/Departure duality is a theorem, not a construction. The Golden Point is νF, there exists a route all of whose continuations remain safe, and the Departure Point is μG. Since $G = \neg F \neg$, the two fixed points are complements outright, so the duality asserted in Definition 4.1 need not be stipulated: it is inherited, and the pair is exhaustive. *The complementarity is a fact about definite states.* The fixed-point analysis lives on the Boolean lattice of definite states, where the result above is exact. An Aethus is a weighted superposition of such states, and what that implies for the categories is taken up in §4.1.4.

Human extinction sits in the difference $\mu G \setminus \text{Base}$. It is not itself a biosphere-level departure by internal or external hazard, since the biosphere persists; but with no muffling agent remaining, every continuation reaches Base (the broader Golden program, set aside here). It therefore enters at the first step of the cascade. The classical reading, that human extinction is a Departure Point because it is only a matter of time, is the $n = 1$ case of the recursion, and (5) is what licenses it.

Remark 4.3 (The model's hazard is a lower bound). The consequence for Section 3 should be stated plainly, since it qualifies every rate in this work. The hazard h_t^{tot} of the survivorship companion [2] is the hazard of Base: it prices the internal and external mechanisms and nothing else. The hazard of *departure* is the hazard of μG, which by (5) is at least as large and in general strictly larger — because a biosphere departs when its fate is sealed, not when the sealing is executed, and the interval between those can be long.

So the model's timescales are conservative in a specific direction: where it reports a departure time T, the Departure Point proper may have been passed considerably earlier, and the survival curves of Section 3 are upper bounds on the probability of not having departed. Nothing in the asymptotic analysis is disturbed by this, a cascade that fires earlier by a bounded lead time leaves exponents untouched, but the quantitative readings inherit it, and the anatomy urgency of the survivorship companion [2] is sharpened by it: the window in which one may still act closes at the cascade's rate, not at the hazard's. Computing that rate is open **[O]**; the schedule of [3] is a first attempt at it, exhibiting the excess as a third hazard channel whose completion weight is a least fixed point the technoanatomy companion [3].

A second approach, complementary rather than competing, is available in the companion and is worth recording here because it constrains what the rate can be. A sealing-hazard is not a hazard on a trajectory but a *settlement* rate on the books: what it prices is the acquisition of statedness by the attribute that the fate is sealed, and that is an event of the present index whatever its referent's date — statedness being a property of the indexing Aethus and never of a clock reading, so that blanks lack tense [5, 7]. Three consequences follow, and the first is restrictive. The weight the current books place on a fixed future-referring attribute is, by the framework's law of total probability, a *bounded martingale* along the progression, the current state prices its own next resolutions, so its expected rate of increase vanishes identically and *the sealing-hazard cannot be a drift.* What survives as a per-unit-time object is the settlement flux, the weight mass absorbed into statedness per unit proper time, together with the direction-blind quadratic-variation rate, which a refined account could consult alongside it. And since a bounded martingale converges, the current weight audits its own hazard: it decomposes into the price of eventual settlement plus the expected never-settled residue, so the number available at

an instant is already an integral over the flux.

That last observation has a consequence for how the open problem should be posed, and it is the one worth carrying. The flux and the level are not rival candidates for *the* sealing-hazard; they are the two ends of a one-parameter family, obtained by pricing settlement at a discount,

$$h_\gamma(B) \;=\; \mathbb{E}_B\big[e^{-\gamma(\rho-t)}W_\rho\big], \qquad \gamma \geq 0, \tag{6}$$

with ρ the earlier of settlement and the path's terminus. At $\gamma \to 0$ optional stopping returns the level itself; at $\gamma \to \infty$ the exponential concentrates and γh_γ returns the instantaneous rate. And the kernel's shape is *forced* rather than chosen: requiring the pricing to commute with refinement of the progression, the price of the children's prices returning the parent's, makes the delay factor multiplicative across concatenated intervals, whose bounded monotone solutions are exactly the exponentials [5].

Two things follow for this work. The exponential of the Cox construction (the survivorship companion [2]) is therefore derivable from partition consistency rather than adopted with it. And this paper already uses both ends of the family without having named them as ends: the survivorship companion [2]'s h^{tot} is a rate, the $\gamma \to \infty$ face; the schedule channel's completion weight the technoanatomy companion [3] is a level, the $\gamma \to 0$ face. Reading them as one family says what the open rate of this remark actually is — not a single number awaiting computation, but a curve whose urgency parameter is itself a modelling commitment, and whose mixtures over urgencies are, by Bernstein's theorem, exactly the completely monotone kernels.

The construction is developed at individual scale in [5], where the settling attribute is lineage termination; what transfers here is the form, by Principle 1, and what does not transfer is any of its quantities.

Proposition 4.4 (One permanent floor suffices; **[P]** given the model)**.** *Suppose some channel h_j of the survivorship companion [2] acquires a* permanent floor*: there are $c > 0$ and t_0 with $h_j(t) \geq c$ for all $t \geq t_0$, no route remaining by which it falls arbitrarily again. Then $\Lambda_\infty = \infty$, so $\mathbb{P}(\Lambda_\infty < \infty) = 0$ and the state lies in μG.*

Proof. The channels are non-negative, so $h^{\mathrm{tot}} \geq h_j$ pointwise, and

$$\Lambda_\infty = \int_0^\infty h_t^{\mathrm{tot}}\,dt \;\geq\; \int_{t_0}^\infty h_j(t)\,dt \;\geq\; \int_{t_0}^\infty c\,dt = \infty. \qquad \square$$

Two things the proof does *not* use are worth marking, since both are tempting and one is false. It uses no property of the other channels: in particular the internal channel need not participate, and a permanent floor in the external channel alone places the state in μG — which is the claim's whole point, that one does not need the base hazard entire. And it does not pass through "$\Lambda_\infty < \infty$ requires $h_t^{\mathrm{tot}} \to 0$", which would be the natural route and is not available: a non-negative function may have finite integral without tending to zero, as tall narrow spikes of shrinking width show. The floor hypothesis makes the detour unnecessary, since it bounds the integrand below on a set of infinite measure directly.

Example 4.5 (Human extinction as an Imperfection Magnitude Drop)**.** Human extinction is an Imperfection Magnitude Drop, and for reasons that are structural rather than sentimental. The grades differ across the parts and are marked where they fall: (A) and (B) below are claims about historical individuation [Φ], their combination with Proposition 4.4 is **[P]** given the model, and the smallness of ε is imported at the companion's grade (Remark 4.8). Two reasons, kept separate because they are referred to separately below:

(A) *The lineage is spent.* The cascade to human evolution ran through the human–chimpanzee last common ancestor, a particular historical individual which no longer exists to be run through again.

(B) *The setting is spent.* The specific sequence of climatic and geographical events that brought that lineage down to the grasslands has been cashed out, the world now standing at a different stage.

The pathway is therefore not merely improbable on repetition — it is *unrepeatable*, its preconditions spent. Two claims must be kept apart here, since the argument moves between them and they carry different values. That *the human route recurs* is not improbable but unavailable: (A) and (B) name stated attributes that are gone, so this contributes nothing at all to what follows. That *the Golden Point is reached without* (A) and (B) is a different proposition, and it is minute rather than zero — an Imperfection Magnitude Drop, in the exact sense the next paragraphs derive. Everything positive that remains after human extinction belongs to the second; the first is simply closed.

The derivation, run on (A) and (B). An Imperfection Magnitude Drop is a targeted perturbation away from one's own Aethus, yielding a natural history whose success-intersection is drastically minute but never quite zero [4, §IMD]. Human extinction complements (A) and (B): the last common ancestor is no longer a stated attribute available to be run through, and the climatic-geographical setting has been cashed out. Any Aethus continuing from that state therefore carries those two attributes complemented.

Two established results then apply, in an order that matters. The High-Contrast Earth Hypothesis fixes the *magnitude*: complementing an attribute correlated with the remainder of the Aethus displaces $P(H \mid \cdot)$ by many orders of magnitude, to an effectively random order — the hypothesis asserting the size of the gap and not its sign [4]. The Accordance Principle then fixes the *direction*, placing ours on the greater side. The perturbed Aethae are accordingly drastically minute, which is what it is to be an Imperfection Magnitude Drop.

Why the deep-time reply does not reach it. "Re-evolving humans is unlikely" invites the answer that deep time makes unlikely things happen, and a post-extinction biosphere has deep time in abundance. That answer would land against a claim about rates. It does not land here, because the displacement is a property of the *perturbation* rather than of a waiting period: complementing a correlated attribute re-randomizes the success-intersection wherever in time the continuation is read, and elapsed time supplies no mechanism returning it to the unperturbed value. The claim is thus made within probability and not outside it, as the Disaster-Difficulty Unification Principle requires — the two sit on the severity spectrum wherever their probability puts them, and what distinguishes them is not their kind but that their probability does not accumulate.

4.1.2 Alternative lineages, by disjointness

The objection that remains is the one about successors: humans will not return, but some other lineage, another primate, or the corvid or cetacean lineages in which complex cognition has arisen independently, might find its own way to the Golden Point. It is answered by the derivation already given, and by a single observation about what such a lineage is.

Lemma 4.6 (Disjointness)**.** *Let L be any extant lineage other than our own, and let A_L be the Aethus of a natural history in which L reaches the Golden Point. The attributes of L mediating*

its route are disjoint *from those mediating (A) and (B): L did not descend through the human–chimpanzee last common ancestor, and was not the lineage driven into the African grassland setting. The disjointness is definitional, what makes L an alternative lineage rather than ours, and it establishes exactly this: A_L carries (A) and (B) complemented, so L is not the human route.*

Corollary 4.7 (Conditional Imperfection Magnitude Drop; **[S]** under the landscape hypothesis)**.** *Under the additional hypothesis that sufficiently route-distant alternatives are Golden-suppressed, the cumulative-suppression package of the High-Contrast Earth Hypothesis and the Optimal-Earth companion [8], each such A_L is an Imperfection Magnitude Drop relative to our own Aethus. Without that hypothesis nothing of the kind follows from the lemma, since a different lineage could reach the same functional capacity by a different route, and the task-object individuation of the task-object construction (Definition 3.9) abstracts from material identity to functional role by design.*

Two clarifications, since the corollary is easy to over-read.

It does not say a successor is impossible. An Imperfection Magnitude Drop is minute and never zero, so A_L retains positive weight for every L. What is claimed is that the weight is displaced by the contrast, not that it is annihilated — and the residual is precisely the ε of §4.1.4. *It does not depend on which lineages are named.* The primates, corvids and cetaceans are referents rather than premises: they say what the disjoint attributes belong to. The proposition would hold for a lineage nobody has thought to nominate, since disjointness from (A) and (B) is a consequence of being a different lineage and not a fact discovered about any particular one.

4.1.3 The conclusion

The assembly runs under the landscape hypothesis of Corollary 4.7, and carries its grade.

The pieces now assemble, and the last step is worth running in full rather than by reference, since it is where a claim about *lineages* becomes a claim about the *Departure Point* and the two are not obviously the same kind of thing. (A) and (B) remove the human route; Proposition 4.6 makes every alternative route an Imperfection Magnitude Drop. Consider then any branch carrying no new muffling agent. On such a branch no route remains by which one re-arises, that is what the two previous results jointly establish, and a channel whose comparisonn depends on an agent that no longer exists and cannot re-arise is a channel that will never again fall. Fix any c below its prevailing value and any t_0 after the loss: $h^{\mathrm{ext}}(t) \geq c$ for all $t \geq t_0$, which is precisely a *permanent floor* in the sense of Proposition 4.4.

That proposition then closes the argument in two lines. Channels are non-negative, so $h^{\mathrm{tot}} \geq h^{\mathrm{ext}}$ pointwise, and

$$\Lambda_\infty \;\geq\; \int_{t_0}^{\infty} h^{\mathrm{ext}}(t)\,dt \;\geq\; \int_{t_0}^{\infty} c\,dt \;=\; \infty,$$

so $\mathbb{P}(\Lambda_\infty < \infty) = 0$. By Definition 4.1 that is the analytic form of the modal claim, no continuation advances, and the state therefore lies in μG. One such channel suffices, and no property of the other channel, of ρ, or of the driver is used anywhere in the step: a single floor anywhere in the total hazard is enough, whatever the rest of the model is doing.

It is worth marking what this does *not* require. It does not require that the floor be high, only that it be positive and permanent; a biosphere left at a very low but irreducible external hazard departs just as surely as one left at a high one, merely later. And it does not require

extinction to be the mechanism — what carries the step is the loss of the *agent*, and any event removing the capacity to muffle without removing the biosphere would carry it identically. On every such branch, therefore, human extinction is a Departure Point *outright* — in the modal sense of Definition 4.1, and not merely a step toward one.

Across the full Aethic weight the statement is graded rather than outright. Positive weight survives on the branches Proposition 4.6 prices, those on which some alternative lineage reaches the Golden Point, and ε is that weight. It is positive because an Imperfection Magnitude Drop is minute and never zero, and small because each such branch takes the displacement of the High-Contrast Earth Hypothesis (Remark 4.8). Its formal statement is §4.1.4.

Remark 4.8 (What carries the argument, and what would break it). The conclusion closes an objection that would otherwise stand against the broader Golden program, set aside here, that a successor lineage might re-evolve the muffling capacity, so the accumulation is inherited rather than forfeited, and it closes it with the same machinery that establishes the drop, not with an additional argument. What is contributed here is only the identification of (A) and (B) as the attributes perturbed, together with the observation that any alternative lineage is disjoint from them (Proposition 4.6); the displacement is then supplied by the High-Contrast Earth Hypothesis and its direction by the Accordance Principle, both imported at the companion's grade [4, 8].

Three things would break it, and they attack different components. That (A) or (B) is misidentified, that the last common ancestor or the climatic sequence is not in fact a stated attribute of the Aethus in the relevant sense, is an attack on this section's own contribution. That the contrast is not vast, or that the interrogated attributes fall outside the correlated class the Hypothesis is scoped to, is an attack on the imported magnitude. And that the direction runs the other way is an attack on the imported Accordance step. The first is where a critic should aim if the target is the present argument rather than the framework it runs on.

4.1.4 Grading, and why two states suffice

The cascade settles what a Departure Point *is*. What remains is that no realistic state satisfies it exactly, since some weight always survives on branches that advance — so the operative statements are graded, and the grading attaches to weight rather than to kind.

Remark 4.9 (The recovery branch: a genuine Aethic superposition, and the grading it supports). An Imperfection Magnitude Drop does not drive the probability of later recovery to zero, and this is definitional rather than incidental: a drop is a perturbation whose success-intersection is drastically minute *but never quite zero* [4]. The weight remaining after human extinction is therefore exactly the drop's residual weight — that of the perturbed Aethae in which the Golden Point is attained regardless. Nothing further is needed to say why it is positive, and nothing further is needed to say why it is small: the first is what an Imperfection Magnitude Drop is, and the second is the displacement of Example 4.5.

That small positive weight sits in apparent tension with a Departure Point defined by a strict modal quantifier: if *some* continuation advances, however faintly, then not every continuation fails, and the label should not apply. *The post-drop state is an Aethic superposition, and that is the whole of the resolution.* An Imperfection Magnitude Drop does not replace one state by another; it produces a state carrying both a departed component and a recovery component, each genuinely stated, in whatever proportion the physics dictates [9]. Neither component is an artifact of description, and neither is deleted by the other being large. The recovery branch is

therefore *present in the Aethus*, not absent from it and merely improbable — which is precisely the condition a strict universal quantifier is sensitive to.

So the label does not attach, and grading is forced rather than chosen. If a component that advances is genuinely stated, then it is false that every continuation fails, and Definition 4.1 does not apply however small that component's weight. What the situation calls for is not a verdict about whether the state is departed but a measurement of how much of it is: the superposition is graded, so the description of it must be graded too. Nothing is rounded and nothing is discarded to reach that conclusion — the grading is read off the state rather than imposed on it.

Remark 4.10 (The graded object at individual scale, and a result that transfers). The definition below has an exact individual-scale instance in the companion, and the companion proves something about it this work does not: for a child B of a state with survival weight s_A, define its *death grade* $g(B) := 1 - s(B)/s_A$, the fraction of survival weight the child destroys. Then the level-price is *affine* in the grade, and a graded slide of grade g is equivalent at zero urgency to a mixture placing weight $q = g$ on total settlement and $1 - q$ on no change [5]. Read across, an ε-Departure Point is a child of death grade $1 - \varepsilon$ at biosphere scale, and the affinity and the mixture equivalence transfer unchanged — which is worth recording because it says the grading is linear in exactly the coordinate the survivor's own accounting uses (the survivorship companion [2]), and not in its logarithm.

Definition 4.11 (ε-Departure Point). A state is an *ε-Departure Point* when the total Aethic weight of continuations that advance is at most ε. A Departure Point in the strict sense of Definition 4.1 is the case $\varepsilon = 0$.

Human extinction is then an ε-Departure Point with ε the weight of the recovery branch — which is to say, in the phrase that states the situation exactly, *almost precisely a Departure Point, probabilistically.* That is a stronger claim than the binary label would have been, not a weaker one: it carries a number where the label carried only a verdict, and it is true where the label was not.

This settles the question the definition deferred.

Remark 4.12 (Where the variation lies). Write $w(A)$ for the total Aethic weight that state A places on continuations which advance. The categories are νF and μG, complementary and exhaustive on definite states (§4.1.1). What varies across biospheres is therefore not *which* category one occupies but *how weight is distributed* across the two: a state at $0 < w < 1$ is a superposition of the pair in the proportion $w : 1 - w$, exactly as Remark 4.9 describes the post-drop state.

Three consequences.

The weights carry what a finer taxonomy would. The framework supplies Aethic weights already, and w is a number where a category would be a verdict; the finer information is in the weight and is available without further vocabulary. *The grading attaches to the state, not to the kind.* Definition 4.11 grades by weight, which is the correct place for grading to sit: an ε-Departure Point is a state whose Departure-tending weight is $1 - \varepsilon$.

Every actual biosphere is superposed, and this is the subject matter. None is secured and none has $w = 0$ while advancing continuations remain, so every case of interest carries weight on both poles. That is also why the technoanatomy companion [3]'s interpolation $\mathbb{P}^{(t)}$ is the right object: it tracks the redistribution of weight between the two, rather than arrival at either.

Remark 4.13 (Where the strictness survives, and the two layers). Two things should be kept apart, because the grading does not reach everywhere.

The model's verdicts remain strict. Within Section 3, the configuration $x \equiv 0$ gives $\mathbb{P}(\Lambda_\infty < \infty) = 0$ *exactly*, and adverse anatomy gives it exactly for every $\rho \leq 0$: these are identities, not small numbers. The ε of Definition 4.11 does not live inside the model at all. It lives at the Aethic level, where the weighting distributes over *which configuration obtains* — and the recovery branch is precisely the branch on which a new muffling agent arises, which the model of a fixed biosphere does not represent. So the model says what happens given a configuration, strictly; the Aethic weight says how much weight each configuration carries.

This is what the two-layer algebra is for. The companion's construction is an unweighted layer carrying the structural facts and a weighted layer laid over it without disturbing them [9]. The cascade of §4.1.1 is a Boolean recursion and belongs to the first: μG is a set, computed from implication alone. The grading of Definition 4.11 belongs to the second. Neither displaces the other. Making the cascade itself graded would require a fixed point of an M-valued doom operator, which is open **[O]** and is the natural next question this remark raises. the technoanatomy companion [3] exhibits one concrete instance of such a fixed point — single-type and carrying one number rather than ranging over the lattice, but computed rather than assigned.

Principle 1 (Continuity; [Φ])**.** The struggle our ancestors underwent against the Departure Point in natural history is continuous, philosophically and ontologically, with a society's agency-mediated struggle against the Departure Point. They are not analogs but the same activity under different mediation.

The Golden Point is the target that respects this, and it does so because of what kind of definition it has: *survival conditioning of its type.* That is primitive enough to apply without alteration to a Mesozoic mammal evading theropod predation and to a modern society avoiding its own weapons. Both lower a hazard; both prevent an Imperfection Magnitude Drop; neither requires the vocabulary of the other. The substance is continuous where the societal construct is not.

Objection 4.14 (Agency)**.** A Mesozoic mammal does not know it is fighting the Departure Point. There is no agency, no goal, no strategy — only an animal avoiding a predator. Calling that continuous with deliberate societal risk-management equivocates on the word "fighting".

The objection assumes agency is what individuates the activity. It is not. By the task-object construction (Definition 3.9), what individuates a task-object is its *contribution to the root*, and agency is nowhere in that criterion — which is precisely why task-objects were required before this principle could be stated. What replaces agency is the mediating mechanism, and Optimation conditions on the mechanism rather than around it. Where a society lowers its hazard through deliberation, a lineage lowers its through evolutionary selection; the conditioning does not care which, because what it fixes is that the hazard be lowered. It therefore reaches *through* the mechanism to whatever contingencies the mechanism requires in order to operate.

Example 4.15 (Conditioning through the medium: the α-gal case; **[S]**)**.** Our α-gal case exhibits the structure exactly, and its details matter because they show the conditioning having no alternative route [4].

Some thirty million years ago the Catarrhine lineage came under pathogen pressure of a particular kind. The pathogen presented α-gal, a carbohydrate our own cells also produced, so that no immune response was available which did not attack the host. What survived carried a

mutation disabling *GGTA1*, the gene responsible for producing it — a gene retained by every other mammalian lineage, and lost in ours alone.[2]

Now read it under Optimation. The gene was ancient and useful, which is why it is universal among mammals; and evolutionary selection removes a gene if and only if there is pressure to remove it. That is the mechanism's own condition of operation, and it is not negotiable. So under ordinary conditions the loss was not merely improbable but close to unavailable: selection had nothing to act on, because the gene was not costing anything.

A conditioning requiring the loss therefore cannot act on the gene. It must act on whatever *supplies the pressure* — and what supplied it was the contingent existence of a pathogen presenting the very carbohydrate in question, which converts the gene from an asset into the one thing standing between the lineage and extinction. Optimation reweights the pathogen's occurrence to prominence, and the loss follows *through* selection rather than around it.

This is the general shape. Optimation does not reach past evolutionary selection to install outcomes; it reweights the contingencies that make selection deliver them. Agency, where it exists, is one such mechanism among others, the deliberative rather than the Darwinian medium, and the conditioning is indifferent between them.

Remark 4.16 (What the principle buys, and its cost). It buys the object the rest of this work analyzes. Without continuity, Section 3's hazard process would model two different things spliced at an arbitrary joint; with it, one process runs from abiogenesis to the present under a single conditioning, and the technological present is a *position* along it rather than a change of subject.

The cost is that the principle is a philosophical premise and not a result, and its scope should be stated at full width rather than left to be inferred, because it is larger than the conditioning question that motivated it. Continuity licenses treating a Mesozoic mammal's evasion of predation, a body's suppression of its own cancers, and an institution's not turning its capacity against itself as values of *one variable*. That is what permits the broader Golden program, set aside here's institutional machinery to bear on Section 3's hazard dynamics at all: without it, the adversivity model would describe the politics of societies and the survival model would describe the fate of lineages, and no argument would carry between them.

So the premise is not merely buying a conditioning target. *It is what makes this one work rather than several.* Should it fail, the sections do not degrade gracefully — they separate, and each retains whatever it had independently while the connections lapse. *Falsifier:* a demonstration that deliberative and evolutionary hazard-comparisonn differ in a respect the conditioning must track — that some feature of the record is explicable under one and not the other. The agency objection is the natural candidate and is answered above; a better one would consist in exhibiting such a feature rather than in restating the intuition. A second and more targeted falsifier follows from the width just claimed: exhibit a hazard-lowering mechanism at one scale whose governing variable provably fails to correspond to anything at another — a property of institutional self-restraint with no analog in organismal or lineage-level hazard control, or the reverse.

[2]The inactivation of *GGTA1* in Old World primates is established, as is pathogen-mediated selection as its leading explanation. The *severity* of the episode, whether it approached extinction of the lineage, is an inference and not a finding, and the argument does not rest on it: pressure sufficient to remove a gene universal among mammals is all that the reasoning requires, and a milder episode delivering that pressure would serve the example unchanged.

The principle transfers form, and not only vocabulary. One further thing the principle does is easily missed, because the statement above is defensive in shape — it says what continuity licenses one to treat as a single variable, which sounds like permission to use a word. It also licenses *inference*, and an instance is now available.

the schedule of [3] represents pre-onset hazard as a sequence of gates. Continuity says the pre-onset struggle and the post-onset one are the same activity under different mediation. It therefore predicts that post-onset internal hazard is representable the same way — that the trough channel of the survivorship companion [2] should decompose into gates, its smoothness being a coarse-graining rather than a fact. the technoanatomy companion [3] carries out the decomposition and finds two things the prediction did not have to deliver: the exponential form falls out of geometric compounding rather than being assumed, and the anatomy trichotomy turns out to be the schedule's own criticality test with capacity substituted for gate count. The construction also agrees with the boundary-scaling derivation of the technoanatomy companion [3], which was arrived at independently.

That is the principle doing deductive work. It did not merely permit the two hazards to be discussed in one vocabulary; it said what form one should take given the other, and the form checked out against a derivation that did not consume it. A reader who regards continuity as a philosophical convenience should notice that a convenience does not generate a correct structural prediction about a channel it was not formulated to describe.

The falsifier stated above is unchanged and now has a sharper instance available: exhibit an internal hazard whose dependence on capacity provably admits no gate decomposition, and the transfer fails at exactly the place this passage claims it succeeds.

4.1.5 Why continuity is wanted: the non-privilege of humans

The principle has now been stated and defended, but not motivated, and its motivation is not tidiness. Continuity is wanted because it is what makes the framework non-anthropocentric, and the non-anthropocentrism is essential rather than incidental[3]. Begin from what the target is. *The Golden Point is a property of a biosphere* — not of a civilization, not of a species. That is why it applies to an alien biosphere as readily as to ours, and applies without translation: nothing in "survival conditioning of its type" mentions humans, technology, or society, so nothing must be reinterpreted when the biosphere in question is not ours.

Proposition 4.17 (Recursive anchoring; **[S]**)**.** *Because the target is biosphere-level and the principle is continuous across mediation, the conditioning may be anchored at* any *Aethus in the lineage consistent with ours. Take a Mesozoic mammal, its Aethus a parent of ours rather than an Imperfection Magnitude Drop, and ask what the continuation of Aethic attributes within* its *future light cone must look like for its biosphere to reach the Golden Point. The answer runs through the remainder of the lineage, and so through us, without us having been named anywhere in the question.*

[3]Provenance, in the author's words: "The reason I decided in 2021 to explicitly build the Optimal Earth program off of conditioning on the Golden Point/asymptotic future survival as opposed to on 'observer existence' is because 'observers' felt profoundly biased as a first principle, whereas something like 'asymptotic survival capacity' felt like something which is perfectly general enough to be fundamental on account of not privileging humans over whatever counterfactual alien species triggers the Golden Point in our place. The intuition behind why this works was itself the space travel argument, where our mere apparent contingency of being able to engage in space travel amidst a biosphere which cannot otherwise do so seems to lock us in as an indicator toward asymptotic survival foremost, and a present day 'civilization' less so."

Our position is therefore an *output* of the conditioning rather than a stipulated anchor for it. Humans are not a privileged split point; the technological present is where the recursion happens to pass, and its role is emergent from a primitive that mentions no species. The same question asked of a mammal in the Maastrichtian, of a lineage that has not yet speciated, or of a biosphere elsewhere entirely, is one question.

Three things a human-centered target would cost. The alternative, conditioning on "technological civilization" or on observers, is not merely less elegant. It forfeits three things, in increasing order of seriousness.

Robustness across biospheres. An alien case would require separate treatment, since the target would be defined by features of our own history. A framework whose central conditioning cannot be applied to the systems it is meant to reason about has not achieved generality; it has assumed its instance. *Robustness across perturbations.* §5.1.2 evaluates histories in which humans do not arise. Under a human-centered target those histories cannot be evaluated at all, the target simply fails to apply, and precisely the perturbations that carry the argument become unaskable.

Non-circularity. A human-centered target takes *us* as primitive, so the framework would build its base unit out of the thing it is supposed to explain. The Continuity Principle is what prevents this, and that is the deepest reason to want it.

A distinction to keep: definition versus conditioning. Two claims are easily run together and must not be, since the argument's validity depends on their separation.

The *definition* of the Golden Point, a survival property of a biosphere, in the sense Section 3 makes precise, is stipulative.[4] Someone who rejects everything else in this section may adopt it,

[4] A dated public record fixes the concept's provenance. The author's grade-school idea journal [10] records the coinage in mid-January 2021, in the eleventh grade: "the point after which our society will be too capable in self preservation to regress past that point," with the surrounding reasoning already survivorship-shaped — constant danger decaying survival exponentially, hence extinction eventually certain without the threshold, which is the survivorship companion [2](ii) in embryo. The same record carries three further anticipations worth a sentence each. "Important can be defined as that which tends to it" is the Score of the decision-theoretic material of the broader program, set aside here as a germ. An August 2021 entry defines "Golden Achievement" as the natural logarithm of the likelihood of reaching the Golden Point, which is the additive log-likelihood structure of the credence method (§7.3) before any of its machinery existed. And a July 2021 notation distinguishes the Miracles elapsed by the modern day from the total "if there are more Miracles needed in the future" — the live-third-term question of [3], posed as a subscript four years before it was taken up as a hypothesis with an evidence route. The record shows the conception arising from the survivorship reasoning alone, with no contact with the future-conditioned cosmological tradition placed at Remark 7.17. A second dated document, the author's *Golden Science* of August 2022 [6], is the link between that coinage and the present formalism, and several of this paper's core objects appear in it by name. Its "Outlook Probability" and "Golden Probability" are the unconditioned and conditioned laws, the $\mathbb{P}/Q$ pair, defined and used; its internal/external division of the Departure Point is the two-channel decomposition of Section 3, with the external channel argued roughly constant and the internal one fed by the biosphere itself; its survival analysis runs on the integrated hazard, computing a positive immortality probability $e^{a/b}$ for exponentially decaying danger, which is the $\Lambda_\infty < \infty$ criterion in closed form; its Third Law is the inequality $b/a < p/(1-p)$ with the L-threshold named — the vocabulary Proposition 5.3 still uses; its "Doomsday Pacing" is the ancestor of the invested-timing role claim of the occupancy discipline of the broader program; Optimation and the task-object both appear as sections; and its "Trace Connection," a placeholder named for "some unknown form of causal (or causal mimicking) connection" between our position and the Golden Point, "until it is officially derived," is the promissory note that retrocausal accordance (the retrocausal-accordance material set aside for a further paper) later paid. The same document also contains reasoning the mature discipline now fences, the every-attribute optimality conjectures among it, so the record documents the corrections as well as the anticipations, which is what a provenance record is for.

and the hazard analysis of Section 3 stands under it regardless.

The *conditioning claim*, that this property is what the Accordance Principle has been conditioning on, is not stipulative and is what §§5.2–5.3 argue for, by model comparison on natural history and again on human history. Running the two together would make the argument circular, defining the conditioning target into its role and then observing that it occupies it. Keeping them apart is what leaves the argument something it could have failed at.

Remark 4.18 (Two non-privilege claims, and their symmetry). The section now makes two claims of this shape, and they are the same claim along different axes. Principle 2 indexes its light-cone restriction to one's own present *because that is where the observable cone is anchored, not because the event is distinguished*; the construction at any other event returns that event's cone. Proposition 4.17 says the same of position in a lineage: the conditioning may be anchored anywhere consistent, and returns that anchor's continuation. No privileged spacetime event, no privileged lineage point — and in both cases the appearance of privilege is an artifact of which cone the reasoner happens to occupy.

Remark 4.19 (A third axis: no privileged tense). The two axes above concern *where* a reasoner stands. A third concerns *when*, and it follows from the same two results rather than needing anything new. We read the ancestral record as a settled chain in which, at juncture after juncture, the beneficial thing happened — which is what conditioning predicts of any cone read from its own end. By Proposition 4.17 the construction is available at any anchor, so an observer anchored far enough downstream reads *our* actions the same way: a settled chain, cropped to their past cone, and by Principle 2 aligned with their own Nexus of Optimation. We are, to that anchor, what the Cretaceous is to us. The distinction between the static record one reads and the dynamic outcomes one produces is therefore not a distinction in the objects. It is an artifact of which cone the reasoner occupies — the sentence the previous remark ends on, now applied to tense.

Two guards, both standing elsewhere in this work and both binding here. *Ensemble, not trajectory.* Nothing in this reweights anyone's actions. Conditioning reweights the ensemble a reasoner is drawn from, and the downstream anchor's reading says which ensemble rather than what any biosphere will do; the broader Golden program, set aside here is disqualifying about the other reading. *And determinacy is indexed to information, not to date.* The downstream cone holds our actions as determinate entries because that anchor has read them; ours does not, and nothing about the reading reaches back. That is exactly the footing on which the companion treats Newcomb's problem, determinacy indexed to an information state rather than to a position in time, so that an unread outcome is a blank entry and blanks lack tense [7], and Remark 6.11's refusal to let a conditioning event *act* is unamended by it.

The relation to Principle 1 is close and is not identity, and the two are easily merged. Continuity is a claim about the *object*: the ancestral struggle and the agency-mediated one are one activity under different mediation. This is a claim about the *reading*: the epistemic relation to that object is the same from any anchor. Neither entails the other, a single activity could be read asymmetrically across anchors, and readings could coincide for activities that were not one, so they are neighbors, and the argument here consumes only the second.

5 The conditioning hypothesis: observer target against Golden target

5.1 What alignment with the target would mean

5.1.1 Statement

Principle 2 (Past-Alignment; [Φ])**.** Construct the *Golden Nexus* by conditioning the Cosmic Nexus on the Golden Point. From it, discard every stated attribute whose referential event lies outside one's own past light cone — in the stricter reading, discarding the spacelike attributes as well as the future-directed ones. What remains is the Nexus of Optimation.

Equivalently: the past light cone of Aethic attributes we actually observe is the same one as the past light cone through our position in the Aethic block universe of the Golden Nexus.[5]

Two features of the statement are deliberate and should not be read past. *The restriction is to the past cone only.* The principle takes no position on whether attributes in one's future light cone agree with the near-optimal part of the Golden Nexus. That silence is not modesty but scope: one cannot reliably infer future-cone attributes prior to engaging in Golden reasoning, so a principle that assumed agreement there would be assuming its own conclusion. Remark 7.7 treats the forward question separately and does not settle it.

The spacetime point is not privileged. The principle is indexed to one's own present because that is where the observable cone is anchored, not because that event has any distinguished status. The same construction at any other event returns that event's cone.

What the principle claims in the companion's own terms. Read against the Optimal-Earth Conjecture [8], the principle sharpens what "optimal" is optimal *for*. The conjecture there holds our record observer-optimal on effectively any interrogable attribute. Past-Alignment says the optimand is not vaguely observer-production but specifically the Golden Point: one asks for the optimal Aethic history *to the Golden Point*, and then surgically reopens every attribute whose occurrence lies in the future cone of the indexing event. If the principle holds, cropping the Golden Nexus to one's past light cone reproduces Optimation exactly — and it is the exactness, not the plausibility, that would make this a first-principles derivation of Optimation rather than a restatement.

5.1.2 The argument from prerequisite attributes

The argument descends from the companion's axioms, and the descent is what makes this paper's central conclusion an implication rather than a posit. Begin inside Nexic reasoning alone [4]. Its Accordance Principle prices any Aethic perturbation that replaces our lineage with a sister clade, dinosaurs or birds or New World monkeys, and asks what becomes of the probability that the perturbed lineage eventually constructs rocket vehicles. The companion's answer is that each such perturbation satisfies a Nexic Imperfection Magnitude Drop, the joint probability of observers and the perturbed history collapsing by the contrast the High-Contrast Earth Hypothesis asserts; §5.3.1 is the worked instance. The construction generalizes past the physically existent sister clades to any *nameable* variation of ourselves obtained by varying a

[5] More precisely than "our actual light cone": owing to random contingency in centric unfolding, our own Aethus is a proper child of the Aetherian Nexus rather than the Aetherian Nexus entire, so the object being compared is the past light cone of the Aetherian Nexus's own Aethic block universe.

stated set of our attributes, and no further: the companion's biological hyperblock cosmos fixes the class of admissible variations, every planet whether existent, hypothetical, or fictional being representable as an alternate history of the Earth on that canvas, and differences outside the class are not perturbations of us at all. The comparison presupposes a common term against which a missing capacity registers as missing, which ordinary object-individuation cannot supply and the task-object construction (Definition 3.9) does: what is compared across histories is a Task-Earth and a task-lineage (Definition 3.9), not an Earth and a lineage. Across the class one quantity behaves the same way. The *disposition* toward reaching another planet, a present capacity rather than a future outcome, drops off for every nameable variant relative to our own value for it, whether the variant is a persisting dinosaur lineage that never reaches the cognitive package, a fungal world lacking the animal capacities the construction requires, or a great-ape lineage left arboreal by a different African climatic sequence. That is a deduction of Nexic reasoning about ourselves, and it is the *pinnacle invariant*: among the nameable variations of ourselves, we hold the highest disposition toward reaching other planets, because each alternative has a lower chance of evolving far enough to acquire the capacity at all. The claim is local by construction, ranging over variations of us and not over the space of describable beings.

Golden reasoning takes the invariant as its deductive root, and the move is a substitution into the companion's own principle. Two features of the Accordance Principle as the companion states it make the substitution available. The principle is stated at a general conditioning target: the draw is asserted between the two middle Aethae of a containment chain $H^* \sqsubseteq H^- \sqsubseteq H^+ \sqsubseteq H$ and not between the record's ends, so that H^+ ranges over targets rather than being fixed at observer-production, and the principle holds at each. And the chain is tense-free: $\sqsubseteq$ is Aethic containment and not temporal order, nothing in the chain requiring one term to fall earlier or later than another in the history's own time, which is the Indiscriminate Time Principle carried into the draw (Remark 4.19). A future-referring conditioning target is one of the targets the principle was stated to range over.

Make the substitution. Let A be the ability to travel in space, a realized attribute of our Aethus and a present disposition, with A' its canonical complement; and let H^+ be the ability to systematically counter cosmic threats, which is the nullification of the external Departure hazard of Section 3 and so is the Golden Point, of which travel in space is a necessary requisite. The Accordance Principle then reads, with no step added,

$$\frac{\mathbb{P}(\text{Golden Point} \mid A')}{\mathbb{P}(\text{Golden Point} \mid A)} \lesssim \frac{\mathbb{P}(A)}{1-\mathbb{P}(A)}, \tag{7}$$

in the exceedance modality the companion's derivation carries, a κ-fold shortfall confined to probability $1/(1+\kappa)$. The right-hand side is where the Nexic deduction enters as the empirical input: $\mathbb{P}(A)$, the weight of the space-reaching disposition under the Cosmic Nexus, is tiny, because across the nameable variations of ourselves the disposition drops off. So futures that reach the Golden Point without our space-reaching capacity are disfavored, relative to futures that reach it with that capacity, by that ratio. That inequality is the Past-Alignment principle at one attribute *under the Golden-conditioned draw*: it states what the record looks like if it is drawn under conditioning on the target, and it is deduced from the companion's principle with that outer measure supplied. Whether our record is so drawn is the hypothesis H_G, and the evidence for it is between-model, the Bayes factor of (8), with the prior bound's tail as the within-model diagnostic; in the critical regime the target is read as the horizon family $\{T > t\}$, per Theorem 3.2.

The substitution runs at any Golden-relevant trait, not only at space travel: any trait of ours may be placed in the A seat, and (7) then prices its complement at the trait's own Cosmic-Nexus weight, provided the trait is identifiable in histories where it does not occur, which is the task-object identification of Definition 3.9. Summed over the traits so interrogated, the result is a local statement about the record.

Corollary 5.1 (Local Golden alignment; **[S]**)**.** *If for every Golden-relevant trait, individuated as a task-object per the task-object construction (Definition 3.9), the perturbed histories depress its Cosmic-Nexus weight, then by* (7) *applied at each trait every tested neighboring perturbation of our Aethus is Golden-disfavored: our Aethus is a coordinatewise local maximizer of the Golden Point's probability among its interrogated neighbors.* Strong Past-Alignment*, that the whole observed past cone is the restriction of a globally Golden-optimal history, does not follow: a landscape can be worse under every one-coordinate move and better under some multi-coordinate one. Strong Past-Alignment is conditional on the cumulative-suppression landscape assumption the Optimal-Earth companion makes explicit [8], and is carried at that assumption's grade, not at this corollary's.*

Remark 5.2 (The grade). The corollary is **[S]** and not **[P]**, for two reasons that are separable. Its inference form is the companion's and carries the companion's grade; what it adds is the chain condition, that a reasoner's Aethus stands in the containment relation to a future-referring target, which is the Route World's own commitment and is graded where that commitment is made ([1]). And it establishes local optimality among interrogated perturbations, not global optimality over the space of histories. What would strengthen it is a perturbation exhibited that leaves a Golden-relevant trait's weight undiminished; what would break it is a systematic class of such perturbations.

Three things follow about the architecture. The Retrocausal Accordance Principle of [1] is the companion's principle at a tense-free target, its display Theorem 3.2 being (7) with the target left general; its [Φ] grade carries the chain condition and not the inference form. The non-circularity is structural: the tense-freeness that licenses the substitution is the companion's, inherited from the Aethic Indiscriminate Time Principle, so Golden reasoning borrows no conclusion of its own, and the rarity $\mathbb{P}(A)$ that fills the right-hand side is deduced under the Cosmic Nexus with no reference to any future. And the choice of target is not free. One might abstract from the space-reaching invariant to maximal capability or to maximal information processing and obtain a different H^+; Departure-nullification is selected because the survivorship companion's mathematics [2] independently picks it out as the fixed point of §4.1.1, the target at which the external channel is driven to zero. Nor, once the target is chosen, are its weights free: the companion takes every weight in the chain as the Cosmic Nexus's, exactly, so that a target padded with content the Cosmic Nexus does not weight carries the weights of the unpadded one; and taking the weights parent-conditional, as the draw does, changes the target's ratio and the attribute's odds by one common factor, leaving the event bounded at a target inside the parent state unchanged [4].

A second consideration selects the same target. The nearby candidate is "technologically advanced civilization," and it fails twice: it admits no principled threshold, and it names a human societal construct with no continuous extension backward through the record the argument must run on. The Golden Point is primitive enough to avoid both failures, being survival conditioning of a stated type, and so stands in substantive continuity with natural history: the same target that a Mesozoic mammal's persistence bears on bears on a launch vehicle, which is Principle 1

and the reason the task-object individuation of the task-object construction (Definition 3.9) is available at every rung. A target one cannot define across the record cannot be conditioned on across the record.

The paper's fundamental conclusion is a further implication of this move and not a separate posit. That our past record is effectively conditioned on our asymptotic-future survival, the Past-Alignment principle of §5.2, the retrocausal instrument of Theorem 3.2, and the strong reading of the Route World all descend from the pinnacle: if the record is such that every nameable variation of us is worse placed to reach other planets, and reaching other planets is a requisite of the target, then the record reads as conditioned on the target. The pinnacle invariant is the inferential root of the Past-Alignment principle.

5.2 The conditioning principle, and the two arguments for it

Past-Alignment as stated is an observation about agreement. The following argues that the agreement is not coincidental — that Nexic natural history was never conditioned on Optimation in the first place, but on the Golden Nexus throughout.

Principle 3 (Golden-Conditioning; **[S]**, by model comparison)**.** Two hypotheses about the outer measure of the record are compared: H_O, that the record is drawn under conditioning on personal observer-existence, and H_G, that it is drawn under conditioning on the Golden Point. A low-probability realization under H_O is not a contradiction of H_O; it is evidence, and the argument is stated as evidence. Consider first what H_O would predict.

Observerhood is robust under Aethic perturbation. One may strip probabilistic prerequisites of the Golden Point, rocket capability, the deliberate governance of the nuclear mode, and replace them by their complements without disturbing one's standing as an observer. A world in which Earth simply lacked the resources to begin an industrial revolution is a world whose inhabitants are no less observers. Now select a handful of such attributes: necessary for the Golden Point, unlikely to survive reopening in the Aetherian Nexus, and admissible in the sense of Remark 6.5 — reopening them must leave the dependent structure intact, so that the resulting Aethae remain individuated by the same task-objects as ours (Definition 3.9). The totality of the counterfactual Aethae so obtained carries *substantially more* Aethic weight than the Aetherian Nexus, while carrying a comparatively minute probability of the Golden Point.

Under H_O the record is a draw from that high-weight counterfactual sum, and ours is a low-weight member of it; under H_G the record is a draw from the members carrying the target's prerequisites, of which ours is typical. The conclusion is a Bayes factor, and nothing stronger. Let E be the conjunction of the technological-route prerequisites so selected, with $\mathbb{P}(E \mid H_O) = q \ll 1$ because observerhood is insensitive to them and $\mathbb{P}(E \mid H_G) \approx 1$ because the target requires them. Then

$$\mathrm{BF}_{G:O}(E) = \frac{\mathbb{P}(E \mid H_G)}{\mathbb{P}(E \mid H_O)} \approx \frac{1}{q}, \tag{8}$$

which is large when q is small *provided* the evidence is highly probable under the Golden model and sufficiently improbable under the observer-conditioned rival; the construction supplies neither likelihood, and the empirical work is establishing those two antecedents. The principle asserts that this factor favors H_G by orders of magnitude, and the weight bound of §6.1 is the estimate of q that gives the factor its size. Both hypotheses are compared after conditioning on the common baseline C the record already fixes, that observers exist now and that the biosphere has survived to the present, so that $\mathrm{BF}_{G:O}(E) = \mathbb{P}(E \mid C, H_G)/\mathbb{P}(E \mid C, H_O)$ and no part of the factor is earned by evidence both hypotheses already had to explain.

5.3 The undeniable case: human history

Principle 3 admits two arguments, and they differ in one respect that decides their order. Both need observerhood to be robust under the perturbations considered — that one can strip prerequisites of the Golden Point without disturbing anyone's standing as an observer. On natural history a sufficiently demanding notion of "observer" can contest that premise (Remark 6.12). On human history it cannot: no one holds that human observers required Alexander's survival, or Newton. Observers existed before each and would have continued after. So the human-history argument is the one on which the robustness premise is simply not deniable, and it is put first for that reason; the natural-history argument follows as the same reasoning in a domain where the premise is contestable and the conclusion correspondingly weaker.

The argument also does something the natural-history one cannot. What these contingencies deliver is not observers but specifically the technological condition — and observer-conditioning is indifferent to every one of them while Golden-conditioning is not. That isolates what the conditioning must be sensitive to, and it says something about the companion that the companion cannot say about itself: its conditioning target, an eventual observer in one's biosphere, is exactly right for the pre-technological record and provably insufficient beyond it. Not a criticism, the companion reads the pre-human record and stops, by design, but the reason for stopping becomes visible only here.

5.3.1 Flukes establish their own significance

Proposition 5.3 (Significance from route-deletion; **[S]**)**.** *Let F be an event established as a* fluke*, of Cosmic-Nexus weight $p < \frac{1}{2}$, whose complement $\neg F$ is route-deleting in the sense of Remark 5.5. Two inferences are not made here: that observerhood is possible without an attribute does not make observer-conditioning indifferent to it, and that something is necessary for our technological route does not make it necessary for every route to the target; the audit identifies the work required and does not complete it, and the single-flip construction transfers the empirical burden to its conditioned probabilities rather than removing it. Under the Golden-conditioned draw, the joint event that F is realized and is the less Golden-productive member of its pair has probability at most p (9): a rare realized route-deleting attribute is unlikely also to be Golden-unproductive. The statement is within-model. Establishing that $\neg F$ is route-deleting rather than a permutation is the case work of Remark 5.5, and evidence that the record is drawn under the Golden target at all is the between-model factor (8).*

The proposition's core is the companion's principle at one choice of κ, and it carries neither the Second Law's translation nor a separate self-sampling step. Taking $\kappa = (1-p)/p$ in the Accordance display collapses its right-hand side to unity and its bound to p, so that

$$\Pr\big[\,\mathbb{P}(G \mid \neg F) \;\geq\; \mathbb{P}(G \mid F)\,\big] \;\leq\; p\,: \tag{9}$$

under the Golden-conditioned draw, the joint event that the rare member is realized and is the less Golden-productive of its pair has probability at most p: fix the member A of prior $p < \frac{1}{2}$; $\mathbb{P}(G \mid A') \geq \mathbb{P}(G \mid A)$ holds exactly when the G-conditioned weight w of A satisfies $w \leq p$, and under $\mathbb{P}_G$ the member A is realized with probability w, so the joint event has probability $w\,\mathbf{1}\{w \leq p\} \leq p$. That is the claim that flukes establish their own significance, and it is a *within-model* diagnostic: it says what a rare realized attribute is, given that the record is drawn under conditioning on the target. It is not *between-model* evidence that the record is so drawn;

that evidence is the Bayes factor of (8) and Proposition 7.18, and the two must not be run together. What the case work of Remark 5.5 supplies is not the significance but the *pairing*: that $\neg F$ is the canonical complement rather than a permutation, so that the attribute whose prior is p is the one whose significance (9) prices.

Proposition 5.4 (The stockpile: accordance on the conjunction; **[S]**)**.** *Let $F_1, \dots, F_n$ be a* predeclared *family of route-deleting flukes with Cosmic-Nexus weights $p_1, \dots, p_n$, and let $F = \bigcap_i F_i$, with complement $\neg F = \bigcup_i \neg F_i$, the union of the counterfactual Aethae. Suppose the family is submultiplicative, $\mathbb{P}(F) \le \prod_i p_i$, which holds with equality under independence and holds under negative association; positive association gives the reverse inequality and defeats the bound. Then under the Golden-conditioned draw*

$$\mathbb{P}_G\big[\, F \text{ realized and } \mathbb{P}(G \mid \neg F) \ge \mathbb{P}(G \mid F) \,\big] \;\le\; \mathbb{P}(F) \;\le\; \prod_i p_i, \tag{10}$$

the joint-event form of (9) applied to the single attribute F: the bound tightens multiplicatively in n while the counterfactual side accumulates weight $1 - \prod_i p_i$, so that ten flukes at $p = 0.1$ each price the joint event at 10^{-10} against a counterfactual union of weight $1 - 10^{-10}$.

The aggregation is where the argument's force lives, and two conditions govern it. Each member must pass the route-deletion audit of Remark 5.5 separately, since a permutation admitted into the conjunction inflates the bound without adding linkage. And the members must be interrogated under a declared scan count, the multiplicity guard of the multiplicity guard of [1] applying to the stockpile as to any member. The guard has two forms and they are kept apart: the expected number of κ-fold exceedances among n interrogated pairs under Q is at most $n/(1+\kappa)$, a bound on Q's own exceedances and not a false-positive calibration for accepting Q against a rival, and the tail is bounded without any independence assumption by Markov, $\Pr[N \ge m] \le n/(m(1+\kappa))$, with the familywise form $\Pr[N \ge 1] \le n/(1+\kappa)$ by the union bound. Exceeding the expectation is not significance; a declared family is scored against the tail.

Remark 5.5 (What the proposition quantifies over, and the counterfactuals it excludes)*.* The template above, F is improbable, we observe it, therefore F is linked to the Golden Point, runs on *any* observed improbability if nothing restricts the range of F, and would then license absurdities: the precise configuration of a Cretaceous raindrop is astronomically improbable and is not thereby significant. The restriction that blocks this governs the proposition's use and is stated before the stockpile that depends on it.

The counterfactual must delete a route, not permute one. Write $\neg F$ for the alternative. The inference is licensed when $\mathbb{P}(G \mid \neg F)$ is genuinely lowered by the substitution, when the counterfactual removes a prerequisite of the Golden Point, and is void when $\neg F$ merely reshuffles which particular events fill the same structural role. The raindrop case is a permutation: some configuration obtains, and every one of them leaves the downstream dependency structure untouched, so $\mathbb{P}(G \mid \neg F) = \mathbb{P}(G \mid F)$ and the bound of Definition 3.1 is satisfied with room to spare rather than violated. Improbability alone therefore establishes nothing; improbability *of a route-deleting attribute* establishes the linkage, and the proposition should be read with that restriction throughout.

The restriction is not free, and it is what the stockpile is selected for. Deciding whether a counterfactual deletes or permutes is a claim about dependency structure and is not delivered by the attribute's weight — which is Remark 7.19's point arriving early: a marginal test on weights

recovers the hubs of the dependency graph, and the route-deleting attributes are exactly the hubs. So the criterion is principled and its application is **[S]**, case by case. This is also the honest register in which the stockpile's items differ. The nuclear disposition of §5.3.3 has the route-deleting character by construction, since past the model's unstable point its complement loses the target at a computed rate, while the Granicus is weaker on exactly this axis, since the claim that no comparable transmission survives Alexander's death at the Granicus is a strong fragility premise about the Hellenistic world and not a computed dependency. The location of British coal, once offered as the strongest historical item, fails the audit outright: on Allen's own counterfactuals the route relocates, to a Dutch–German or Belgian industrialization, rather than disappearing [11], and Calibration I of §6.1.1 reaches the same verdict from geology. The criterion thus removes an item the narrative favored, which is evidence that it discriminates.

Remark 5.6 (The retrospective-target null, dissolved by the principle). The strongest rival to the proposition is not the determinist's substitutability but the *retrospective-target* null: any realized history, read backward, contains improbable events that were prerequisites of whatever that history's distinctive features happen to be, so a stockpile of flukes pointing at the realized outcome is expected under no conditioning whatever, the sharpshooter who paints the target around the shots. The null is answered not by argument but by the form of the Retrocausal Accordance Principle (Theorem 3.2), which was built so that the two freedoms the fallacy exploits are closed and its residual content is priced. The first freedom is the choice of target, and the principle's B is not drawn from the record: it is the Golden Point, picked out by the fixed-point structure of §4.1.1 as a future-cone attribute defined before and independently of which record obtains, so the target stands before the shots in the only sense the null requires. The second freedom is the choice of reference class, and the principle's A' is the canonical complement of the realized attribute, so nothing about the alternatives is analyst-supplied and no class can be drawn to make the realized value look rare. What the null correctly observes is then exactly what the principle's exceedance form Theorem 3.2 quantifies: rare attributes that are irrelevant to B do abound, they violate the bound, and the principle prices each such violation at probability at most $1/(1+\kappa)$, so that among n interrogated attributes up to $n/(1+\kappa)$ κ-fold exceedances are expected under Q itself, a bound on Q's own exceedances and not a false-positive calibration for accepting Q against a rival, which is the sense of the multiplicity guard of [1]. The null is thereby absorbed rather than refuted: its content is a term in the principle's own accounting, and a trace standing clear of the floor is evidence while one within it is the expected noise.

Three further answers to the null are corollaries of the same form. That consistency with a hypothesis is not evidence for it over a rival the same data fit, the comparative point of §7.5, is the principle's left side read literally: an attribute is evidence only through the ratio $\mathbb{P}(B \mid A')/\mathbb{P}(B \mid A)$, and an attribute whose complement leaves B as likely as before fails the bound and is counted as noise, which is the route-deletion-against-permutation question of Remark 5.5 stated as arithmetic. And that the human-history leg's distinctive content lies in flukes that are prerequisites of the technological condition specifically, to which observer-conditioning is provably indifferent, is the identification of which attributes have $\mathbb{P}(B \mid A') \ll \mathbb{P}(B \mid A)$ under the Golden target and not under the observer target: it is where the ratio discriminates the two conditionings, and raw improbability never was the currency. One discipline the dissolution does not remove, because it is what the floor is for: the scan count must be declared. The null returns, in full force, against any reasoner who interrogates attributes freely and reports only the flags, and the principle's guard is an instrument only when n is on the table.

The dinosauroid, answered (worked case; [S], one import at [Φ]). The question whether the dinosaurs could have evolved into humans, posed in its classic form as the dinosauroid [12] and generalized in the debate between contingency and convergence [13, 14], receives a direct answer once its vague target is replaced. "Evolving to intelligence" is not a well-posed endpoint; "acquiring the capacity to trigger the Golden Point" is, and with that substitution the framework's answer is no, by deduction rather than by paleontological intuition. The classic rejoinder, that some birds are strikingly intelligent, is met on its own terms: a lineage may become smart along one metric or another without ever rising to high capacity for high Golden-Point probability, and the delicate Golden-leading activities, rocketry as the emblem, would never have entered its realm of possibility. The companion's Imperfection-Magnitude-Drop argument [4], an IMD being a targeted perturbation of one's own natural history whose observer-production probability is drastically minute, sharpens "less" to "vastly less": such a lineage's Golden-Point probability would sit far below our own, so that with the vast majority of the likelihood it would have become smart, if at all, along a tangential metric. The substitution also dissolves the standoff it was borrowed from. Convergence may well hold for cognition along some metric, as its defenders argue, while contingency holds at the level that matters here, because Golden capacity is a delicate, Miracle-coupled competence and not a convergent target; the two camps were arguing about different endpoints under one word.

The case is the flukes proposition's canonical instance, and it shows the route-deletion criterion doing its case work rather than being asserted; it is also the worked instance of the pinnacle invariant from which §5.1.2 descends the conditioning principle. The end-Cretaceous impact is the fluke F, the world in which the dinosaurs continue is $\neg F$, and the claim that $\neg F$ carries vastly lower Golden-Point probability is the claim that F was route-deleting rather than a permutation, which is exactly what Remark 5.5 requires to be established case by case. The "birds" objection is the substitutability reading of Remark 5.7, answered here by the metric distinction. One pitfall must be avoided, and the companion names it: the naive counterfactual "no humans" removes the conditioning on us, and with it Optimation, so that the counterfactual Earth destabilizes quickly and the comparison becomes trivial. The comparison is therefore run already conditioning on Earth maintaining its habitability, and the answer survives that concession, which is what gives it force. The structure is the natural-historical mirror of the extinction proposition (the broader Golden program, set aside here): remove the muffling lineage and the background stands unmuffled, in the deep past as in the counterfactual present.

Remark 5.7 (This settles the contingency-determinism debate, in one direction). Historians divide over whether the path to modernity was contingent or overdetermined, and the dispute is usually conducted by weighing narratives. Proposition 5.3 makes it an inference. The determinist holds that the apparent flukes were substitutable: no Alexander, then someone else; no Newton, then Leibniz and Hooke. Substitutability is exactly high b, a good chance of the Golden Point without F, hence low Golden Linkage, hence $g \approx p$, hence the expectation that we occupy $\neg F$. The Third Law, the Accordance bound of Definition 3.1 with H the Golden Point, bounds it quantitatively: $b/a < p/(1-p)$, so the flukier the event, the more severely substitutability is constrained by our observing it. The determinist is not refuted by a better narrative; they are constrained by an inequality whose inputs are the event's improbability and its route-deleting character (Remark 5.5) — nothing else.

5.3.2 The stockpile

One historical case, one withdrawn, and one that requires reframing. *A single sword-stroke.* At the Granicus in 334 BCE, two months into an eleven-year campaign, the Persian noble Spithridates brought a battle-axe down on Alexander's helmet and split its crest; Cleitus the Black severed his arm before the second blow [15, 16]. Had the stroke landed, the expedition would have ended within days of beginning, and with it the Hellenistic world, its Alexandrias, and the transmission through which much of what followed ran.

A withdrawn case: where the coal happened to be. Earlier drafts placed a second historical item here, the location of British coal, on Pomeranz's account of England as a "fortunate freak" whose coal lay near water and ports while China's lay far from the Jiangnan economy [17], and on Allen's of the labor-to-energy price ratio under which mechanization paid in northern Britain [11]. It does not survive the route-deletion audit of Remark 5.5. Those accounts explain where and when industrialization began, not whether it could begin: Allen's own counterfactuals relocate it to the Low Countries and the Rhineland, and Calibration I below finds coal-bearing basins on nearly every continent. The case is kept as the instrument's first negative result and not as a member of the stockpile. The strongest member is instead contemporary, the nuclear disposition of §5.3.3, whose route-deletion is a theorem of the hazard model rather than a historian's judgment.

A further case is available but requires reframing. Diamond's account of Eurasian advantage [18] is *determinist* at the level of human history, geography made the outcome near-inevitable, and is criticized on that ground. What the present argument takes from it lies one level down: the distribution of domesticable species and the continent's east–west axis are contingent *across possible Earths* while determining *within* ours. That is precisely the Accordance profile, low outlook probability with high Golden Linkage, and Diamond's determinism is at the wrong level rather than mistaken.

5.3.3 A post-observer attribute of the present: the nuclear disposition

The stockpile's historical members are joined by one contemporary member, and it is the cleanest, because its route-deleting character is a theorem of a hazard model rather than a historical judgment. The model, its proofs, and the author's provenance are the Golden companion's [19].

The attribute. Let the internal hazard h carried by the nuclear mode switch its anatomy between a favorable value ρ_+ while the mode is governed deliberately and an adverse value ρ_- while it is not, with crisis feedback raising the rate at which governance is lost linearly in h, as $b_0 + b_1 h$, against a rate of return a. The mean dynamics then have two equilibria, separated at $h^* = (\rho_+ a - \rho_- b_0)/(\rho_- b_1)$: below h^* the mode is driven down, and above it the hazard spirals and annihilation is avoided only by luck. The attribute E is being in the stable basin with a floor of favorable anatomy. Its complement deletes the route, the Golden target being lost past the unstable point at a rate of at least h^*, so the route-deletion audit of Remark 5.5 is passed by construction.

The evidence it carries. Let C be the observer baseline, $w = \mathbb{P}(E \mid C)$ the weight of the Golden-compatible class over the counterfactual routes to an observer-grade lineage, G_T the horizon family of the Golden target, and $r_T = \mathbb{P}(G_T \mid \neg E, C)/\mathbb{P}(G_T \mid E, C)$. By Bayes, the factor favoring the Golden-conditioned draw over the observer-conditioned one is

$$\mathrm{BF}_T(E) = \frac{\mathbb{P}(G_T \mid E, C)}{\mathbb{P}(G_T \mid C)} = \frac{1}{w + (1-w)\, r_T},$$

rising to $1/w$ as $T \to \infty$, since $r_T \to 0$. Observer existence contributes no factor: every counterfactual route reaches observers whatever its nuclear anatomy, so the attribute is of the class *post-observer, pre-Golden*, on which the two conditionings separate. What the argument does not have is w **[O]**, the weight of the favorable class over a route class declared independently of the outcome; and the factor never exceeds $1/w$, so the attribute is evidence and never certification.

5.3.4 Why this leg is the stronger one

Two reasons, and the second is the more important. *The robustness premise becomes uncontroversial.* The natural-history comparison needs it granted that observers survive the removal of the end-Cretaceous impact, which can be resisted. Nothing comparable is available here. No one holds that human observers required Alexander's survival, or Newton. Humans existed for millennia before each and would have continued after their removal. The premise that carried the weight and could be denied is here simply not deniable.

The conclusion sharpens. What these contingencies deliver is not observers but specifically the *technological* condition — skyscrapers, the internet, the capacity to leave a dying star. Observer-conditioning is indifferent to every one of them; Golden-conditioning is not. So the human-history argument does not merely repeat the first at lower risk; it isolates what the conditioning must be sensitive to.

Remark 5.8 (The narrative-bias objection, and the test that answers it). The serious objection is selection in the record rather than in the world. Dramatic near-misses make better stories, are more often written down, and are more often repeated; a history dense with them may report a fact about historiography. The framework predicts an asymmetry that narrative bias does not, and the prediction is already on record. Attributes with high Golden Linkage magnitude but *low connectivity* to other attributes should have low Golden Probability — lucky avoidance of adversity outranks lucky survival of it, so isolated close calls should be *rare* in the record while densely connected contingencies should be *numerous* [6]. Narrative bias inflates both alike; the framework inflates one and suppresses the other.

The discrimination turns on a plain prediction: *the strongest cases should be the dull ones.* Nobody narrates price ratios, paper supply, or the reach of literacy, and if undramatic, densely connected contingencies of that kind turn out to be the well-attested route-deleting items, narrative selection cannot be what generated the pattern. The test has not yet been run. The one dull item first offered, the location of British coal, failed the route-deletion audit (Remark 5.5; Calibration I of §6.1.1), so the file is to be assembled dull entries first and the prediction scored on what survives. The framework is exposed here: if, so assembled, the dull entries prove substitutable and only the vivid close calls survive the audit, narrative bias is the better explanation of the record's texture. The Granicus remains the vivid illustration, and the contemporary nuclear disposition of §5.3.3, whose route-deletion is computed rather than narrated, is the strongest member at present.

Both legs concern the past cone, and neither speaks to the future. That silence is deliberate, §5.1.1 recorded it as scope rather than modesty, and the three positions available on the forward question are set out next without adjudication.

6 The natural-history leg: the counterfactual weight, bounded

6.1 The contestable case: natural history

The same comparison, run on the natural-historical record. Its premise, that observerhood survives the perturbations considered, is contestable here in a way it was not above, and the argument is correspondingly the weaker of the two; it is included because it reaches further back, and because it is where the conditioning claim was first posed.

The Trace Connection, named in 2022. The claim this subsection advances was posed as an open problem, under its own name, four years before the present argument. Our *Golden Science* of August 2022 [6] sets out the Golden Principle in four numbered points, of which the third states that our observations are far closer to representing those of an average Golden-Point biosphere than those of an average position in the universe, Past-Alignment in prose, and the fourth states that some connection, causal or causal-mimicking, holds between our existence at this time and place and the Golden Point itself. That paper then names the connection and declines to supply it: it is to be called *the Trace Connection* until it is officially derived.

§5.2 is offered as that derivation. What the 2022 statement supplies, and what no later argument could manufacture for itself, is that the gap was identified, named, and dated before any candidate filling existed — so the comparison cannot be read as having been reverse-engineered to fit a conclusion already in hand. The same document also carries, in prose and without the stochastic apparatus of Section 3: the hazard-function framing of biosphere survival; the observation that an exponentially decaying hazard yields a strictly positive limiting survival probability; the division of the failure mode into internal and external channels, together with the insistence that a Golden biosphere must lessen *both* rather than either; the thesis that domination is inefficient because it feeds the internal channel, which is Φ3; the Kardashev critique including the self-consumption argument; and the definition of the Golden Point as the point past which a biosphere cannot regress, drawn there against the Hubble horizon. The formal content of Section 3–the broader Golden program, set aside here is later; the apparatus it formalizes is not.

Corollary 6.1 (What remains; **[S]**)**.** *What the comparison leaves standing is the empirical artifact of Past-Alignment itself: conditioning on the existence of the Golden Point somewhere in the Aethic block universe reproduces exactly the inferential form of the Accordance Principle that yields the stated-attributes of Nexic reasoning. Among the contingent natural histories one might find oneself at the end of, a fungal world, a dinosaurs-survive world, a wholly lemurine one, the one that must be conditioned on to reproduce the Nexic state of affairs we actually observe is the one in which the Golden Point exists.*

Remark 6.2 (A second robustness, and why the target's modal form was the right one). Principle 3 turns on a robustness: observerhood survives perturbations the record does not, so a conditioning indifferent to the difference cannot have produced the difference. The schedule channel of the schedule of [3] exhibits a second target with the same defect, and it is nearer to hand than observerhood. *Survival to a finite horizon is robust in exactly that way.* A biosphere may survive any stretch one names without having climbed its schedule at all — by not being struck, at bare background, on the lucky branch that the technoanatomy companion [3] shows never leaves the support of a finite-horizon conditioning. So conditioning on having-lasted leaves

the record unexplained for precisely the reason conditioning on observers did: it is satisfied by histories in which nothing was climbed.

What survives the objection is the asymptotic form, and the point worth extracting is that the target was already stated in it. Definition 4.1 gives Goldenness as $\exists\forall$, some course admits *no* foreclosing continuation, which is a condition on the whole of a future and not on any initial segment of one. A reading of the Golden Point as a passage completed at some finite time would have inherited the robustness above and failed here. The modal form is therefore not a technical nicety of the definition; it is what makes the target capable of doing the work Principle 3 asks of it. Stated as content, that asymptotic form is the Golden Aethus of Definition 7.3.

The cost is recorded rather than absorbed: this raises what the conditioning must be, and by Theorem 3.6 no one is entitled to know that it obtains.

6.1.1 Bounding the counterfactual weight

The comparison of 3 turns on a single inequality: that the counterfactual Aethae obtained by reopening Golden-Point prerequisites carry substantially more weight than the Aetherian Nexus. Stated bare, that is an assertion, and an objector may simply deny it — perhaps coal is common given a Carboniferous, perhaps the metallurgical sequence is near-forced given hands and fire. This subsection replaces the assertion with a construction, a bound, and a statement of exactly what empirical input remains outstanding.

The construction. Fix stated-attributes $a_1, \dots, a_k$, each a prerequisite of the Golden Point and none a prerequisite of observerhood. Let $\mathcal{A}$ denote the Aetherian Nexus, in which every a_j obtains, and let $\mathcal{A}_j$ denote the Aethus obtained by reopening a_j alone to its logical complement, holding the remaining $k-1$ at their realized values.

Lemma 6.3 (Disjointness; **[P]**)**.** *The Aethae $\mathcal{A}_1, \dots, \mathcal{A}_k$ are pairwise disjoint, and each is disjoint from $\mathcal{A}$. For $j \neq j'$, the pair $\mathcal{A}_j$ and $\mathcal{A}_{j'}$ disagree on* both *slot j and slot j'; and $\mathcal{A}_j$ disagrees with $\mathcal{A}$ on slot j.*

Proposition 6.4 (Weight ratio; **[P]**)**.** *Write α_j for the probability that slot j takes its realized value, conditional on the remaining slots taking theirs. Then*

$$\frac{W(\mathcal{A}_j)}{W(\mathcal{A})} = \frac{1-\alpha_j}{\alpha_j}, \tag{11}$$

and by Lemma 6.3 the single-flip Aethae may be summed:

$$R \;:=\; \frac{W_\times}{W(\mathcal{A})} \;\geq\; R_1 \;=\; \sum_{j=1}^{k} \frac{1-\alpha_j}{\alpha_j}. \tag{12}$$

Remark 6.5 (What the bound does and does not require). Three features of (12) are worth isolating, because they are what make it usable.

Independence is not required. Only disjointness is, and that holds by construction. Dependence among the a_j changes what the individual ratios *are*, the α_j become conditional rather than marginal, as stated, but not whether the terms may be added. This matters because the attributes at issue are plainly not independent, and an argument needing them to be would be unusable. *It is a lower bound, and deliberately a loose one.* The single-flip Aethae are a vanishing

fraction of the counterfactual set, and the full sum over all Aethae differing in at least one slot is larger by many orders; it has no closed form for dependent attributes, since $\prod_j \mathbb{P}(a_j \mid a_{-j})$ is not $\mathbb{P}(a_1, \ldots, a_k)$ without a factorization assumption, and none is imposed. The comparison needs only that $R \gg 1$, which the single-flip sum supplies exactly.

Admissibility is governed by the Imperfection Magnitude Drop criterion. A perturbation enters the sum only if it leaves the dependent structure intact — if reopening a_j does not re-randomise what depends on it. A perturbation that triggers a drop does not yield a clean single-slot flip, and Lemma 6.3 fails for it. Coal lying inaccessible everywhere is admissible on this criterion: it may be probabilistically catastrophic without re-randomizing the structure downstream. A relocation of the lineage's speciation to another continent is not, since the material that later mediates the outcome is not present there to be held fixed.

How large must R be, and how improbable must the attributes be? The comparison requires only $R \gg 1$. Evaluating (12) for k attributes each at probability α:

α	$k = 1$	$k = 3$	$k = 5$	$k = 8$
10^{-1}	9	27	45	72
10^{-2}	99	297	495	792
10^{-3}	999	3.0×10^3	5.0×10^3	8.0×10^3
10^{-4}	1.0×10^4	3.0×10^4	5.0×10^4	8.0×10^4

The bar is far lower than the informal argument suggested. A *single* attribute at $\alpha = 10^{-3}$ delivers $R \sim 10^3$ unaided; no portfolio is needed, and the burden reduces to establishing one prerequisite as genuinely improbable. Correspondingly, the objection that the counterfactual sum might be comparable requires *every* candidate prerequisite to have α of order one, that the metallurgical sequence, the governance of the nuclear mode, and the rest are each more likely than not given the rest of the record, which is a considerably stronger claim than the objection is usually asked to bear.

Estimating α: the sister-case method. The remaining empirical input is supplied by an instrument the companion already develops, and it should be used rather than reconstructed [4].

By the Theorem of Aimless Optimation, Optimation is the Cosmic Nexus conditioned on the attribute H_N that an Aetherian exists in one's biosphere; and if an attribute X is statistically independent of H_N, the two Nexae assign it the same weight. Independent attributes are therefore *controls*: their observed frequency estimates the Cosmic Nexus probability directly, unlifted by conditioning. The companion's worked case is the Catarrhini node — Old World monkeys furnish over a hundred extant species across twenty-five million years with no attainment of ape-level intelligence, and their fate being independent of H_N, that frequency transfers as the baseline for our own lineage at the same node.

This is exactly the quantity (12) requires. For an attribute a_j admitting such a control, α_j is read off the control's frequency, and its contribution to R_1 follows.

A corollary on once-only attributes, and the independence check that governs it. A corollary of the same theorem bears on attributes observed exactly once, and it should be read as an inference rather than a consistency claim. Once a first occurrence has secured what

the Golden Point requires, a *second* occurrence is statistically independent of H_N, it changes nothing about whether an Aetherian exists, and by the theorem it therefore retains its Cosmic Nexus weight and is not lifted. Optimation supplies what is required and does not overshoot.

The consequence is a discriminating observation. Write λ for the unconditioned expected count across all opportunities. Under the hypothesis that $\lambda \ll 1$, Optimation must lift the attribute for H_N to obtain, and lifts it to exactly one; *exactly one occurrence is what that hypothesis predicts*. Under the hypothesis that no lift was needed, occurrences are Poisson at rate λ and exactly one is a coincidence of probability $\lambda e^{-\lambda}$. The likelihood ratio between them is $\left(\lambda e^{-\lambda}\right)^{-1}$:

λ	1	3	5	10	20
ratio favoring lift	2.7	6.7	30	2.2×10^3	2.4×10^7

So a single occurrence tells strongly against the configuration having been *common* — $\lambda \geq 5$ is disfavored thirtyfold or worse — while discriminating only weakly between a genuinely minute λ and one of order unity. Its evidential role is accordingly to exclude the objection that the prerequisites were unremarkable, not to supply the magnitude. The magnitude comes from the independent per-opportunity estimate, and where that gives $\lambda \ll 1$ the attribute contributes approximately $1/\lambda$ to R_1.

The corollary is only as good as its individuation, and this is where the difficulty sits. Rather than proceed directly to an estimate, we calibrate the instrument on two attributes for which the data are good. Both return nothing, and the pattern in *how* they return nothing is what fixes the strategy.

Calibration I: coal. Britain's coal is the obvious first candidate, and it fails at the endowment grain. Carboniferous and younger basins are known on virtually every continent, the Appalachians, the Ruhr, the Donets, the Kuznetsk, the Nord-Pas de Calais–Saar–Lorraine field, and others, giving eight or more on any reasonable individuation, and Britain's is not the most favorable, the Appalachian seams being unusually large and unusually exposed. With $\lambda \approx 8$ we obtain $\alpha = 1 - e^{-\lambda} \approx 0.9997$ and a contribution to R_1 of about 3×10^{-4}: nil.

The verdict is confirmed by the author whose thesis is most at stake. Allen observes that the Ruhr went unexploited not for want of coal but because Dutch peat held fuel prices down, removing the return on improving Rhine transport; and he draws the counterfactual explicitly, that had German coal been developed three centuries earlier the industrial revolution might have been a Dutch–German achievement rather than a British one [11]. He identifies Belgium, around Liège and Mons, as possessing a comparable ratio of wages to energy cost. So the claim that the path to the twentieth century ran through northern Britain was always about the *conjunction* of cheap energy with dear labor and the institutions to exploit both — never about the seams, which were widely available. A reader who recalls that claim should read it that way, and the estimator's verdict agrees with Allen rather than contradicting him, reached independently and from geology. This is why the coal is no longer a member of the stockpile (§5.3.2).

Proposition 6.6 (The bound on *parallel* attributes; **[S]**)**.** *The two failures share a cause, and it is structural rather than accidental. Call an attribute* parallel *when its opportunities are a set of co-existing sites, landmasses, basins, continents, so that $\lambda = Np$ with N the site count. For an attribute individuated at continental scale, $N \approx 5$. To obtain $(1-\alpha)/\alpha \sim 10^3$ then requires $\lambda \sim 10^{-3}$, hence a per-site probability of order 2×10^{-4} — a claim that cannot responsibly*

be defended for any attribute of the form "this landmass possesses feature X". Deep time can deliver minute λ for parallel attributes because its site count is astronomical; recent history cannot, because its site count is five.

Coal and megafauna are both parallel attributes. That, and not their recency, is why they failed.

Serial attributes escape the bound. Proposition 6.6 is a claim about parallel attributes only, and the restriction is not a technicality — it identifies the wrong turn that coal and megafauna represent. An attribute may instead be *serial*: a conjunction of successive branch points within a single trajectory, each of which had to go one way for the next to be reached.

Proposition 6.7 (Serial attributes; **[S]**)**.** *Let an attribute consist of m successive branch points, the ith resolved favorably with probability p_i conditional on its predecessors. Then $\alpha = \prod_{i \le m} p_i$ and the contribution to R_1 is $\alpha^{-1} - 1$, which grows* exponentially in m. *At $p = 0.75$ throughout: $m = 8$ contributes about 9, $m = 16$ about 99, and $m = 25$ about 1.3×10^3.*

The opportunity structure is what differs. A parallel attribute is bounded by how many sites exist, and there are five continents. A serial attribute is bounded by how many branch points the trajectory contains, and a well-articulated historical episode contains many. Recent history is therefore not weak evidence; it was being individuated in the form that makes it weak. This is how the candidates should be stated. Not "Alexander existed", which is a parallel attribute of no force, but *that he survived and succeeded through the entire sequence*, the wound at the Granicus, Issus, Gaugamela, the near-fatal injury among the Malli, the absence of a disabling illness before consolidation, and the Hellenization surviving the immediate fragmentation of the empire, each a branch point with its own p_i. Likewise the Roman survival of the Second Punic War is a sequence, not a fact: the recovery after Cannae, Hannibal's failure to march, the holding of the Italian allies, Scipio's African campaign. Likewise the passage of Christianity from a provincial sect to an imperial religion, and its part in what followed. Each such episode is one attribute in (12), and each carries a contribution set by the length of its cascade rather than by the number of continents.

Remark 6.8 (What serial attributes cost)*.* The gain in magnitude is paid for in the independence check, and the price should be stated plainly, since it is where such an estimate would fail. For each branch point one must hold that its failure had no adequate *substitute* — that had Alexander died at the Granicus, the Hellenization of the East does not simply proceed under another commander. History is rich in substitutes, and each p_i that admits one contributes nothing, since the attribute is then not load-bearing for H_N at that step. The estimator's discipline accordingly transfers from grain, where it sat for parallel attributes, to substitutability.

Two consequences follow. Cascade length must be counted in *substitution-free* branch points, not in dramatic incidents, which will reduce m considerably below the narrative count. And the per-step probabilities must be conditional on the predecessors, since the steps are plainly not independent — a commander who has survived four battles is not a random draw at the fifth. Both corrections push α upward, and a careful estimate should expect the eventual contribution to fall well short of the naive product.

Remark 6.9 (Individuate the branch point by its role, not its occupant)*.* The substitutability audit has a corollary that governs how each branch point must be *stated*, and getting it wrong is the most likely route to an inflated estimate. The counterfactual at each step must be taken over the *role*, not over the occupant. The question at the relevant branch point is not whether

Christianity in particular arose and spread, but whether *anything* arose that discharged the role it discharged — in the window, with the reach, and with the consequences for what followed. So individuated, the competing cults of the period are not rivals to the hypothesis but candidate fillers of the same role, and their availability raises α at that step rather than lowering it: where a role admits κ independent candidates each of probability q, the role-probability is $1-(1-q)^{\kappa}$, not q.

Role individuation is therefore the *conservative* choice, and that is precisely its merit. It concedes the substitution objection in advance rather than meeting it afterward: a critic who replies that some other movement would have served is not refuting the estimate but restating the quantity already being estimated. What survives such an audit is a residue of steps at which no filler was available with comparable probability — and the claim, where a cascade is offered, is about that residue.

It also relocates where improbability may legitimately be found. It is not to be sought in the striking identity of the occupant, which is where narrative attention naturally goes, but in the narrowness of the window in which *any* occupant could have appeared. The transitional periods are the interesting ones for that reason, and the dramatic incidents largely are not.

Remark 6.10 (The limitation is present ignorance, not the structure)*.* One further point about the status of these estimates, and it cuts in an unusual direction. The obstacle to evaluating $\prod_i p_i$ for any actual cascade is not that the quantity is ill-defined or that the method is unsound. It is that counterfactual history is not yet in a state to supply the p_i with defensible error bars — the substitutability audits and the window widths that Remark 6.9 requires are matters on which the discipline has views but not measurements. The uncertainty is *ours*, and contemporary; it is not a property of the cascades.

Two things follow. The paper should not, and does not, offer a numerical cascade estimate: what it offers is the structure (12), the serial–parallel distinction, and the individuation discipline, with the arithmetic left for inputs that do not yet exist. And the expectation that such inputs will exist is a substantive bet rather than a certainty — one that quantitative counterfactual history will mature to the point of supplying audited branch-point probabilities. If it does, the enumeration becomes routine and the bound follows. If it does not, the weight claim remains structurally established and empirically unfilled, which is a weaker position than we would like and a stronger one than assertion [**O**].

An unnamed significance is a prediction, and it has a falsification test. Remark 6.10 leaves the framework in a position that looks, at first, like an unfalsifiable auxiliary. We do not know what the establishment of a universalizing cult in the late-antique Mediterranean forced through downstream; the analysis nonetheless concludes that something Golden-relevant was forced through, on the strength of 5.3 alone. Stated carelessly this is the canonical bad move — every fluke acquires an unnamed significance, nothing counts against the framework, and the Accordance analysis becomes a device for dignifying whatever happened.

It is not that, and the reason is that the unnamed significance is a *prediction* with a definite content and a definite refutation. *Content.* For a cascade C satisfying the two admissibility conditions, genuinely improbable, and load-bearing in the sense of Remark 6.9, the claim is that there exists a consequence of C on which the probability of the Golden Point depends, and that it will be identified. The claim is made before the consequence is known, which is what makes it a prediction rather than a description.

Refutation. Exhibit a route to the Golden Point that does not require C. If the terminus is

reachable without the cascade, then C was not load-bearing for it, and the predicted consequence does not exist to be found. This is the substitutability audit of Remark 6.8 run at the *terminus* rather than at an intermediate — which is the only place it can be run when the intermediate is unnamed, and which is a harder audit rather than an easier one, since the chain to be traced is longer.

And the criterion is diachronic. A single unnamed significance is a debt; a growing ledger of them is a symptom. The framework is progressive if the ratio of identified to unidentified consequences improves as counterfactual history matures, and degenerating if the unnamed list only lengthens while the named one does not. We state this as the test we intend the program to be held to: *if the historiography improves and the significances remain unnamed, that counts against the framework and is not to be absorbed by it.* The passage of time is thereby made a test rather than an excuse, which is what the position in Remark 6.10 would otherwise lack.

One asymmetry should be noted, since it limits what confirmation is available. Failure to exhibit a C-free route is weak evidence at best, because such routes are counterfactual claims subject to the same immaturity that motivated the remark. The test is therefore one-sided in the ordinary way: it can refute a particular significance claim and cannot establish one, and the framework's standing rests on whether the identifications accumulate.

The consequence: aggregate, but of serial attributes. The comparison requires $R \gg 1$, not $R > 10^3$, and R_1 is a *sum*. Even under the corrections of Remark 6.8, a modest stockpile suffices: twenty attributes contributing about ten apiece give $R_1 \approx 200$, and a single well-attested cascade may supply as much on its own.

attributes	each ≈ 5	each ≈ 10
10	50	100
20	100	200
40	200	400

So the program is an enumeration of serial contingencies, each articulated as a cascade and each audited for substitutability. The record supplies candidates readily — the military sequences above; the demographic rupture of the Black Death and its effect on the very wage structure Allen's account requires; and the theses of [18] beyond megafauna, several of which admit serial rather than parallel statement. What the two calibrations established is not that recent history is barren but that it must be interrogated along the trajectory rather than across the map.

Why the negative calibrations are retained. Two attributes were examined and both returned nothing. It would be tidier to omit them, and it would be a mistake. They demonstrate that the instrument has teeth. A method that never returns nothing cannot discriminate, and a reader entitled to suspect that the estimator was constructed to deliver a congenial answer is answered by two cases where it did not. They also fix the grain discipline *before* any positive estimate is offered, so that the eventual stockpile is credible rather than convenient. And they preempt the two objections a reader arrives with, that coal was surely the scarce thing, and that Diamond's asymmetry surely settles the matter, with the estimator's verdict rather than with assertion.

Most importantly, the pattern in the two failures is itself the finding. Had one failed and the other succeeded, the first would read as a red herring. Both failing, and failing for the same reason, is what establishes Proposition 6.6 and thereby the aggregation strategy. The negative

results carry the argument. This is where the argument's remaining empirical debt sits, and it is now specific and bounded. What (12) establishes is the structure: given the α_j, the bound follows. What Proposition 6.6 establishes is that no single recent attribute will supply it, so the debt is a stockpile of order twenty contingencies, each estimated by the sister-case method and each passing the independence check. The weight claim is accordingly no longer asserted but *conditionally computed* — reduced from a plausibility judgment about an unexamined sum to an enumeration of bounded terms, each obtained by an instrument calibrated in advance and each with its required magnitude stated **[O]**. What remains owed is the enumeration, and *that* is a research task rather than an argumentative gap: the terms are individually modest, the sources are identified, and the standard each must meet is fixed before any is computed.

Remark 6.11 (The conditioning is not teleological). A reader's first objection will be that conditioning on a future event to account for present observations is teleology: the Golden Point reaching backward to arrange its own prerequisites. The framework answers this at its foundations rather than here, and the answer should be cited rather than improvised.

The relevant result is the *indiscriminate time principle*, a corollary of the extrusion principle [5], whose content is a pair of mutual non-informations: knowing where the events an attribute's blanks refer to sit in space and time tells one nothing about when those blanks resolve for oneself, and knowing when they resolve for oneself tells one nothing about where they sit. Blankness is a property of the indexing Aethus, never of a clock reading — *blanks lack tense*, and an observer's unlearned past is exactly as open as their unformed future [20].

The objection therefore rests on a premise the framework denies. It assumes that the Golden Point's futurity makes it a different kind of object from an unresolved attribute of the past — that the not-yet-real is a category. On the Aethic account there is no such category: the Golden Point is a blank attribute relative to our Aethus, in precisely the sense that an unread outcome of the deep past is blank, and conditioning on it is the same operation in both cases. The asymmetry one feels is real but *entropic* rather than ontological: the future blocks discriminating information more stringently because it sits downstream of the entropic arrow, while the past merely happens to withhold it — and informational uncertainty is the same thing under either obstruction [5]. The companion records at **[O]** a further conjecture on this asymmetry, that the entropic arrow is itself the past-ward limit of the asymptotic-future survival conditioning, the past hypothesis being the conditioning's shadow rather than a posit [6].

The mirror-image case matters, because it is a structure the reader can check without granting anything particular to this work. Newcomb's problem conditions on a *past* event, the predictor's sealed placement, which is blank relative to the agent's information state; and any treatment on which the agent's decision bears on that placement must decline the assumption at issue here, that a past occurrence is thereby a settled fact. Past-Alignment conditions on a *future* event that is blank relative to ours. Same operation, opposite direction, and by the indiscriminate time principle the direction is not a difference. A reader who accepts the one and rejects the other owes an account of which of the two mutual non-informations they mean to keep.[6]

What the Golden Point does here is therefore what any conditioning event does: it selects, and does not act. The Aetherian Nexus is not *caused* to contain rocketry by a later passage; the weighting conditioned on that passage assigns overwhelming weight to histories containing

[6]The companion treatment is [7], which develops the Newcomb case on exactly this footing: determinacy indexed to an information state rather than to a position in time, so that an unread past outcome is a blank entry and blanks lack tense.

it, and we read the record we are in. Whether anything stronger than selection holds, whether the future cone is constrained rather than merely uninformative, is exactly what Remark 7.7 declines to settle, and the Void hypothesis is the position on which nothing stronger holds at all.

Remark 6.12 (Why this is not circular, and where it could fail). The obvious objection is circularity: conditioning on the Golden Point and then finding its prerequisites is no achievement, since the prerequisites are what the conditioning selects for. The objection would land against a bare appeal to Past-Alignment, and it is worth being explicit that it does not land here, because the argument of 3 is *comparative* rather than confirmatory. Two candidate conditioning targets are placed side by side; they issue *different* predictions about the record, one indifferent to industrial prerequisites, one not, and the record discriminates between them. A comparison that could have gone the other way is not a circle.

Three ways it could fail, in decreasing order of seriousness. The weight claim remains the decisive one, though §6.1.1 has reduced it from an assertion to a single measurement: the bound (12) is proved, and one prerequisite at $\alpha \sim 10^{-3}$ suffices, so what would remove the contradiction is now the specific demonstration that *every* candidate prerequisite has α of order one. Second, the argument requires "observer" to be robust under exactly these perturbations; a sufficiently demanding notion of observerhood, one entailing industrial capacity, say, would collapse the two conditioning targets together and dissolve the comparison, though at the cost of making "observer" do work it is not usually asked to do. Third, the comparison establishes that the target is *not* observer-existence; that it is specifically the Golden Point is supported by Past-Alignment rather than forced by the contradiction, and some third target could in principle serve.

Both arguments are now in hand. The natural-history one carries the weakness Remark 6.12 flags, its robustness premise is contestable, and the human-history one of §5.3 does not; a reader who accepts only the second has accepted the principle, and the first is then the same inference extended into deeper time.

7 The Route World: what the strong reading predicts

Section 5 established that the record we hold is the past-cone restriction of a conditioning on an event in our future cone, and left open which of three hypotheses governs the forward cone. This section develops the strongest of them, the *Route World*, in which the Golden Point stands as a stated attribute of one's Aethus rather than as a weight over futures, the world of the Golden Axiom (Axiom 1), and does so because it is the one hypothesis with a phenomenology. If it holds, a biosphere approaching its Golden Point experiences not fewer improbabilities but more, of a specific kind; that is a claim about the texture of the near future, and unlike almost everything else in this work, a claim about ours.

Everything here is [**O**], with one stated exception: the conduct argument, which belongs to the Golden program's practical layer and is not reproduced here, and which is [Φ] on an adopted valuation and argues for the hypothesis exactly as little as the rest. The section describes what the hypothesis predicts, states what would distinguish it from its rivals, disciplines the historical reading, connects the answer to the epistemic ceiling, and names, without deriving it here, the conduct the open hypothesis leaves an agent; it argues for the hypothesis nowhere, the one argument for it in this paper being the author's Paradox of Departures, recorded in its own section at its grade (Section 8). What it supplies is the framework's most distinctive prediction, and a reader should not finish this work without knowing the strong reading has one.

Void has been given a form it could take (Remark 7.8), and Weak a statement of what its two refusals commit it to (Remark 7.9). Strong needs something different in kind. Void and Weak needed their commitments drawn out, whereas Strong's difficulty is that it has no empirical handle at all — its three metaphysical questions are stated at Remark 7.10, and none of them is a question any observation bears on. This section supplies the handle by describing the world Strong asserts. The description is a consequence of the hypothesis and not an argument for it.

Definition 7.1 (The Route World; **[O]**)**.** The *Route World* is the world of the Strong extrapolation hypothesis: the world in which the Golden Point stands as a stated attribute of one's Aethus rather than as a weight over futures, the world in which the Golden Axiom holds (Axiom 1), so that the conditioning is resolved throughout the cone and not merely behind one. The name is meant in the sense *RNA world* is meant — a regime with a characteristic phenomenology, described so that one can ask whether one is in it.

Remark 7.2 (Whether "stated" is coherent for a future-cone attribute)*.* The definition invites an objection that must be met before anything is built on it. The framework rejects tensed determinacy: an unresolved future outcome is a blank entry, and blanks lack tense. How can an observer then hold as *stated* an attribute whose referent lies in their future cone — is that not the very error the framework was built to avoid?

It is not, and the reason is that the objection reads "stated" as "resolved by the clock," which is the tensed reading the framework denies. Statedness is a property of the *index*, of what the observer's books carry, and not of the referent's date (Remark 4.19). An attribute is stated when it is a fixed entry of the Aethus, whatever its referential event's coordinate; a stated attribute with a future referent is no stranger than a stated attribute with an unobserved past referent, and the framework has carried the latter since its first postulate. What the Strong hypothesis asserts, the Golden Axiom (Axiom 1), is that the Golden Point is such an entry for us, fixed in the books, not merely weighted, and *that* is a substantive claim about which Aethus we hold, not a category error about tense.

The analytic form of the same point is already in this work. the technoanatomy companion [3] distinguishes the interpolation $\mathbb{P}^{(t)}$, a family whose conditioning is still being acquired, from Q, a single measure whose conditioning has been absorbed into the base state — and identifies the passage to Q with the statement of a future-referring attribute in present books, the statement the Golden Axiom makes of one's own books at every proper time at once (Remark 7.5). The Route World is the world in which that passage has occurred. Weak is the world of the family; Strong is the world of the measure; and the difference between them is exactly the difference between an attribute weighted and an attribute stated, which the framework can express and does not collapse.

7.1 The Golden Axiom

The Strong hypothesis has so far been stated in the vocabulary of statedness: the Golden Point is a stated attribute of one's own Aethus. Its two load-bearing words each conceal a choice the framework makes for a reason, and the hypothesis is worth stating once in the framework's own primitives, as a single named axiom, so that the choices are visible and everything that consumes the hypothesis can point at one place. "Stated in" is the parent relation of the Aethic order, and the thing stated is not a passage completed at some finite time but survival through every proper time. The axiom below is that statement. It is an axiom in the mathematician's sense, a statement taken as a starting point and derived from nothing else here, and stating it is not

asserting it: this subsection states it, prices it, records the author's account of why it and no weaker statement is the Golden one, and marks what consumes it, in keeping with this section's discipline of describing the strong reading rather than arguing for it. The author's argument that the axiom holds of us is recorded separately, in Section 8.

Definition 7.3 (Survival attributes, and the Golden Aethus at its primitive)**.** For $\eta \in \mathbb{R}$, the *survival attribute* at proper time η is the attribute that one's own biosphere survives at least through proper time η: in the model of Definition 3.4, the event $\{T > \eta\}$, with T the departure time, departure and not death being the quantity, since a biosphere departs when its fate is sealed and not when the sealing is executed (Remark 4.3). The *Golden Aethus*, stated at its primitive, is the Aethus $\mathfrak{G}$ that states the survival attribute at every proper time $\eta \in \mathbb{R}$, with every other attribute genuinely blank: the asymptotic survivorship conditioning on the universe, stated as content. In the set notation of ordinary intuition $\mathfrak{G}$ reads $\bigcap_{\eta\in\mathbb{R}}\{T > \eta\} = \{T = \infty\}$, indefinite survival.

The Golden Point of Section 4 is this attribute's event-form, and the two carry one attribute. The Golden Point and the Departure Point are complements on definite states (Remark 4.2, **[P]**), so reaching the one is the only route by which the other is avoided; a biosphere that reaches the Golden Point admits no foreclosing continuation and so never departs; and the Golden Point is the state past which viability obtains (Definition 3.4), which indefinite survival forces. The identification is carried at the framework's usual grades and not at **[P]**; the $\exists\forall$ form of Remark 6.2 is what lets the event stand in for the asymptote at all. Where the record's perturbation arguments are run, the event form is the one consumed; where the conditioning itself is stated, the asymptotic form is primitive, and it is the one the axiom uses.

Axiom 1 (The Golden Axiom; *exposed postulate*, **[O]**)**.** It is a parent Aethus to one's Aethus that the universe is conditioned on one's biosphere surviving at least through proper time η, for all $\eta \in \mathbb{R}$. Formally, with H^* one's own Aethus as in the chain of §5.1.2,

$$\boxed{H^* \sqsubseteq \mathfrak{G}} \tag{13}$$

in the refinement order of the Aethic tree: one's Aethus is state-decomposable as $H^* = \mathfrak{G} \cdot C$ for some Aethus C, which is what it is for the survival attributes to be stated in it. Equivalently, by Definition 7.3, the Golden Aethus is a parent Aethus of one's own. Relative to one's Aethus the weighting is then the Cosmic Nexus conditioned on $\mathfrak{G}$'s stated content, which is the Golden Nexus (Principle 2).

Remark 7.4 (Why a parent Aethus: the first postulate)*.* The natural first statement is that *the universe is conditioned on the infinite survival of one's biosphere*, and it is Aethically ill-defined. The Aethic companion's first postulate holds that any attribution of reality is a statement of relation to a particular Aethus [5]: there is no Aethus-free ledger of facts, and the structure over Aethae, which Aethae are valid and what weights attach, stands un-indexed. The bare sentence attributes a conditioning to the universe as such. Read as a claim about the un-indexed structure it is false by construction, since the Cosmic Nexus absorbs no conditioning; read as content, it is content with no Aethus for it to be a relation to, which the postulate does not admit. Stated as a parent Aethus of one's own, the conditioning is content, and is indexed exactly where the postulate requires it: the survival attributes are entries of one's Aethus, and the universe is conditioned relative to that Aethus and not absolutely.

The parent relation is the refinement order and not the stricter proper-child order. Refinement is childhood itself, $B \sqsubseteq A$ exactly when $B = A \cdot C$ for some C [5, 9], so that "a parent Aethus to one's Aethus" says that one's Aethus decomposes with $\mathfrak{G}$ as a factor, that is, that $\mathfrak{G}$'s content is stated in it; whether one's Aethus is also a visible term of some declared decomposition of $\mathfrak{G}$ is a further question the axiom does not ask. And the parent form keeps the sentence indexical in the way its words already are, *one's* Aethus and *one's* biosphere: a successor agent's books would state its own survival attributes, a different object.

Remark 7.5 (Why every proper time). Each survival attribute at a finite η is an ordinary attribute of positive probability. Below the biosphere's origin it is vacuous; up to the present it is already in the record, the common baseline C of Principle 3, that the biosphere has survived to now; beyond the present it lies in one's future light cone, and stating it in present books is no stranger than stating an unobserved past attribute, statedness being a property of the index and not of the referent's date (Remarks 4.19 and 7.2). The axiom's content beyond the record is therefore exactly its future-cone part, and it is retrocausal only in the dry sense of being conditioned on an Aethus lying in one's future light cone.

The quantifier over every η is what makes the axiom state the asymptote and not an initial segment of it, and nothing weaker would serve. Finite horizons select the schedule but never exclude its absence, while the asymptote excludes it at the level of support [3]; and conditioning on having lasted to a finite horizon leaves the record unexplained for the reason conditioning on observers did (Remark 6.2). At any finite η the non-Golden class keeps positive odds, at most $((1-\alpha)/\alpha)\, e^{K-\Delta\eta}$ by Theorem 3.8, and only the quantifier over every η sends them to zero.

The family form also says how the conditioning is constructed. In the critical regime $\mathbb{P}(T = \infty) = 0$, so that conditioning on $\{T = \infty\}$ names no elementary conditional probability; each $\{T > \eta\}$ has positive probability and is conditioned on in the ordinary way, and the measure that has absorbed every one of them is $Q = \lim_{\eta\to\infty} \mathbb{P}(\,\cdot \mid T > \eta)$, the survivorship companion's Q-process [2], a single measure where the interpolation $\mathbb{P}^{(t)}$ is a family still acquiring its condition (Remark 7.2). This is the horizon family through which Theorem 3.2 reads a survival target. In the viable regime $\mathbb{P}(T = \infty) > 0$ and $Q = \mathbb{P}(\,\cdot \mid T = \infty)$ outright. Stated in present books, the axiom is the passage to Q: the ill-definedness the parent form removes is Aethic, and the one the family form removes is measure-theoretic.

Remark 7.6 (Why this axiom is the Golden one: it deduces the past cone; **[S]**, the author's account). The axiom earns its name, on the author's account, because it deduces the Nexic companion's deductions about the attributes of our past light cone, and does so from survival alone: no humans, no civilization, and no technology enter it, only a biosphere and the time it lasts. Condition on survival to a horizon η and split the histories into those that climb the prerequisite schedule to completion, the route up the Nexic evolutionary ladder that carries exotic structure to the Golden Point, and those that survive without climbing, by not being struck at bare background. At short horizons the second class dominates, the climb being a minute-probability route; but its survival weight decays exponentially while the climbing class's does not, and past the technoanatomy companion's survival-time threshold, $T_* \approx \log(1/p)/(B+\Gamma)$, the conditioned law favors the climb, rarity entering only through $\log(1/p)$, so that a one-in-a-trillion climb moves the threshold by about $28/(B+\Gamma)$ and no more [3]. Nor does the account need the climb's tail to be polynomial: the author's theorem behind it, Theorem 3.8, shows that survival conditioning selects any fractional lowering of the total hazard, however small, bought by any structure, however rare, past a horizon that grows only as the logarithm of the rarity and inversely with the drop. A drop by a fraction δ of the floor stretches the

threshold by $1/\delta$ and no further, so that a one-in-a-trillion structure buying a one-per-cent drop brings the odds below one in a million at $\eta_* \approx 4.1 \times 10^3/h_{\min}$, against $41/h_{\min}$ for a complete drop. Applied pairwise, the theorem orders any two classes by their drops, so the asymptote selects the class of greatest drop. That is the sense in which the Golden Point's necessity is emergent: conditioned on survival through every proper time, the Golden class, of prior weight α, carries weight one, and the weighting that states every horizon at once concentrates on records that carry exotic structure. The past-cone restriction of that weighting then displays the Nexic companion's natural-historical content, its Optimation, its coupled improbabilities, and its Accordance constraints, as the record of a climb: Past-Alignment (Principle 2) derived rather than observed.

The class that does not reach the Golden Point is not a residue of near-misses. Exotic structure short of the Golden Point buys no survival: an incomplete schedule leaves the biosphere at bare background with the internal channel at its full coefficient [3], so that such histories survive only by luck, at the rate of histories with no structure at all, and the class's conditioned weight is held overwhelmingly by histories of high biological entropy, with a barren Earth from the beginning as the author's limiting case. That is why the Golden Point, and not exotic structure as such, is where the weight turns, and why its importance in this framework is metaphysical and not only prudential. It is also the class against which the Paradox of Departures prices a departure (Section 8).

Remark 7.7 (The axiom and the three hypotheses). Three positions on the forward question are available to a reader who grants Past-Alignment. *Void*: the alignment of our past cone with the Golden Nexus is a brute coincidence, and nothing constrains the future cone. *Weak*: there is an explicit distribution over futures, each proper child Aethus weighted by some function of its probability of the Golden Point. *Strong*: the Golden Aethus is already stated in one's own Aethus, and has been since the beginning of centric unfolding; contingency remains in which route is taken, but outright Aethic disjointness from the Golden Point is forbidden.

Strong is the Golden Axiom held at every stage of centric unfolding. Its first sentence is (13); its clause that this has been so since the beginning of centric unfolding is the axiom at the unfolding's earliest Aethus, which gives it at every later one by the transitivity of refinement, since centric unfolding only accrues stated content and each later Aethus refines every earlier one. Strong therefore implies the axiom at every present, and the axiom at the unfolding's start is Strong. Strong's prohibition of disjointness is the axiom's contrapositive: an Aethus disjoint from $\mathfrak{G}$ cannot refine it, a refinement stating everything its parent states. The Route World (Definition 7.1) is the world in which the axiom holds, and Remark 7.2's defence of statedness for a future-cone attribute is the defence of the axiom's coherence. Weak denies the axiom and keeps a weighting, the survival attributes beyond the present weighted over one's own proper children and not stated, which is the interpolation $\mathbb{P}^{(t)}$; Void denies that anything constrains them. Neither is the bare negation of the axiom, each adding a positive claim about what holds in its place. Past-Alignment does not need the axiom, being a claim about the past cone that holds or fails under all three; what the axiom adds is that the agreement it reports is entailed rather than coincidental, the record being the past-cone content of an Aethus that states the conditioning.

Remark 7.8 (How Void could look: a proposal, not an adjudication; **[O]**). Void is stated as a denial, that no law or inferential rule constrains our forward cone, and a denial has no ontology. Since the infinite-horizon reading of Remark 7.5 raises its price, it is only fair to record that a positive form is available which pays that price rather than evading it. What follows is a

proposal about how Void *could* be realized, offered without endorsement and without prejudice to the other two.

The construction. Let the conditioning event be region-indexed in its own statement: attributes whose referential events lie in the past cone are constrained as one conditioning would have them, attributes elsewhere as another. This is not two operations — a conjunction of region-indexed constraints is a single event in the product space, and conditioning on it is one act. Read as a gate: *if past-cone, condition on A; otherwise on X*. A smooth interpolation between the two regimes serves as well as a step and is the more natural object.

The weakening that makes it work. A need not *be* the infinite-survival condition. It need only approximate it closely enough that Principle 2 is observed — and Past-Alignment is an empirical claim about what the record looks like, which more than one event can produce. So A may be categorically distinct from infinite survival while agreeing with it to within observational reach, and Void's forward denial becomes the claim that X departs from A where nothing has yet checked.

What that buys. The natural objection is over-determination: every region is eventually some observer's past cone, so a later observer treats as past-conditioned what an earlier one treated as future-conditioned, and consistency would force $X \equiv A$ everywhere — collapsing the construction into a single conditioning. Under the approximation reading it does not bite. The two need only agree *approximately* on regions that are somebody's past, and approximate agreement is compatible with categorical distinctness. The objection bites only against the strict identity, which the construction does not assert.

The constraint that remains. Whatever indexes the gate cannot be a distinguished spacetime position: Proposition 4.17 lets the conditioning be anchored at any Aethus in the lineage and returns that anchor's continuation, and Remark 4.18 forbids privilege outright. The index must therefore be schematic — computed by every observer from their own anchor and yielding the same partition of their own cone. That is not an obstacle so much as a specification: an anchor-invariant index is available, since a goldening interpolation whose windows are a fixed fraction of a biosphere's own history is age-relative.

And the coincidence need not be explained. If the transition is quasi-abrupt and falls near our position, Void owes no account of why. That is not evasion within Void's own terms: its thesis is that such alignments are brute and uninfluential, and a hypothesis whose content is bruteness pays in brute facts by design. The fair scoring is that this is a cost by ordinary lights, three brute facts where the hypothesis as stated carried one, and not a cost by Void's, and a reader will weigh those differently depending on what they think explanation is for.

Where it risks collapsing into Weak. The smooth version's danger is that a graded conditioning strength over futures is a weighting of futures, which is Weak's position and not Void's. Whether daylight remains turns on whether the interpolation index is a function of Golden-Point probability. This work keeps those apart, $\mathbb{P}(\Lambda_\infty < \infty)$ being the probability of advancing rather than of not dying (departure and not death is the quantity, Definition 7.3), so the gap is real but narrow, and a proposal of this kind should be checked against it before being relied on.

None of this adjudicates. It says only that Void has a form available in which it is a positive hypothesis about what the conditioning event is, rather than a refusal to say; and the form leaves open exactly what the rest of this paper leaves open, which is what the conditioning actually is.

Remark 7.9 (Weak as the intermediate, and what each refusal commits it to; **[O]**). Symmetry requires the same treatment of the remaining hypothesis, and Weak turns out to be the most structurally constrained of the three — its position is fixed by two refusals, each carrying a

commitment it cannot decline. *Refusing Void commits Weak to privileging the Golden Point.* If some rule constrains the forward cone, Weak's is indexed to Golden-Point probability and to nothing else — so the Golden Point is not one outcome among many but the quantity that sets the measure. This commitment is shared with Strong, and it is what separates both from Void: the forward question's first division is whether the Golden Point indexes anything ahead.

Refusing Strong commits Weak to our contingent position doing work. Under Strong the conditioning is already fully resolved and every anchor returns the same settled object, so where one stands is inferentially idle. Under Weak the distribution is over *one's own* proper children, so the anchor does real work. That second commitment needs care, because stated carelessly it collides with Remark 4.18. It does not. What non-privilege forbids is a metaphysically distinguished position at which the conditioning is anchored and nowhere else. Weak's anchor is *schematic*: every Aethus indexes its own distribution over its own children, by the same rule, and Proposition 4.17 says precisely that the conditioning may be anchored anywhere and returns that anchor's continuation. Weak is therefore not in tension with recursive anchoring but is the hypothesis that takes it forward.

Which admits a sharper statement of Weak's position than the definition gives. *Weak is the only one of the three under which recursive anchoring has forward content.* Under Void there is nothing ahead to anchor; under Strong anchoring makes no difference, since all anchors return the same resolved object; under Weak each anchor returns a different distribution over its own children, and the differences are the hypothesis's whole content.

One consequence for the Aetherian Nexus, which requires a distinction the section has not yet drawn. Principle 3 demotes observer-conditioning as an *explanation* of the record: observerhood is too robust under perturbation to have produced it. That leaves untouched a second role. Something must specify where "we" are, and Principle 2's own footnote already leans on the Aetherian Nexus for exactly this, noting that our Aethus is a proper child of it rather than the Nexus entire. *Target* and *index* are different offices, and failing at the first says nothing about the second. Under Weak the index does forward work, since the distribution is over the children of a position the index picks out — so the Aetherian Nexus recovers a standing under Weak that it has under neither of the others, without any part of the comparison being withdrawn [4].

And the costs, since the other two have had theirs stated. Weak owes an argument for its functional form: the definition says the weight is proportional to *some function* of Golden-Point probability, and any increasing function would serve, with nothing yet selecting one — so the hypothesis as stated is a family rather than a position. It owes an account of how the index is computed, which the schematic reading requires be available to every anchor alike. And its weighting is *relative*, a share of a total the hypothesis does not bound, so it inherits without amendment the technoanatomy companion's caution that a collapse onto one ordering is a claim about shares and not about likelihood [3]: that a future carries the largest share of the forward measure is not that it is likely, and comparison by an Accordance-like metric is comparative in exactly the sense that supplies no absolute reassurance. None of the three is supplied here.

Remark 7.10 (Three questions the Strong hypothesis raises). If the Strong hypothesis holds, three metaphysical questions become pressing and none is answered here **[O]**: why future-cone Aethic information should be available at all; how and why that information is so intimately bound up with the initiation of centric unfolding, being perhaps its earliest and leading piece of Aethic content; and what the implications are for the entropic principle of Aethic reasoning and its account of how the past is distributed between past and future Aethic cones. A conjectured answer to the third, that the entropic arrow is the past-ward limit of the asymptotic-future con-

ditioning, is recorded in the Golden program's ontological development and consumed nowhere. Deriving either of the second or third from the other would be a natural line of attack.

Remark 7.11 (What the axiom does not say)*.* It does not say that anything acts. The conditioning does not act, choose, or design (Remark 6.11); the verbs remain *is conditioned*, *is reweighted*, and *is selected*; and the axiom reweights ensembles and not paths. It is not a forecast for the clock: it says neither that the Golden Point will be reached by any date nor that anyone will see it reached, but which Aethus one holds, and in a world where it holds the survival attributes are determinate in the books and inaccessible to the reasoner, two predicates of two objects (Remark 9.1). It is not idealism: the Golden Aethus is nobody's mind, and statedness is a property of an index and not of anyone's access. And it certifies nothing. Since Q and $\mathbb{P}$ agree on every finite window, no finite observation establishes the axiom (Theorem 3.6), and the unavailability is one-sided in the way the ceiling's always is: the infinite record that would settle it is held only by a biosphere that persists to obtain it.

The axiom's price. In the Nexic companion's format [4]. *Posited*, not derived: an exposed postulate, **[O]** as a claim about which Aethus we hold, with the author's argument for it, the Paradox of Departures, at **[S]** (Section 8). *Buys*: everything this section marks as the strong reading's, the Route World's phenomenology, Golden Optimation (Definition 7.12), Golden causality (Definition 7.15), the empirical signature with its limits (§7.3), and the extension from events to constitution recorded among the fences (§9.1). *Refuted by*: the departure of one's own biosphere, a survival attribute failing at some finite η, which is Aethic disjointness from $\mathfrak{G}$ — a refutation no member of the departed biosphere is placed to certify, departure preceding and being separable from death, and one whose weight the Paradox of Departures prices; and, short of refutation, the evidence of §7.3 running against it, which by the ceiling never certifies either way.

7.2 Golden Optimation, and where it differs

The Route World's signature is a strengthening of a phenomenon the companion already names. Optimation reports that a record conditioned on observerhood displays flukes against the Cosmic Nexus's own rates [4]; but those flukes lie, at every moment, in the observer's *past* cone, because the conditioning event, one's own existence, is behind one. The supply is bounded by what has already happened.

Definition 7.12 (Golden Optimation; **[O]**)**.** *Golden Optimation* is the same phenomenon under a conditioning event in the future cone. Because the Golden Point lies ahead, the flukes its occurrence requires need not have occurred yet: there are moments at which a given required fluke lies in the observer's future cone, and the observer's moving present passes over it.

That is the whole differentia and it is sharp. Classical Optimation never predicts a fluke; it accounts for flukes already in the record. Golden Optimation predicts them, because the conditioning event has not yet occurred and the requirements it imposes are still being met. A Route World is therefore a world in which one keeps encountering improbabilities *prospectively*, and the rate at which one does so is the hypothesis's observable content.

Remark 7.13 (One phenomenon, and the label is tense-relative)*.* The two Optimations are not two mechanisms with a seam between them. Take a fluke F required by the Golden Point, occurring at Aethic time t_F, and an observer at t. For $t < t_F$ the observer's present has not

reached it and F is Golden Optimation; for $t > t_F$ it stands in the record and is Optimation in the companion's sense. *Same event, same conditioning, different label* — and what changed was the observer's position, not anything about F.

So the label tracks the observer and not the phenomenon, which is Remark 4.19 applied to Optimation: an observer far enough downstream reads our Golden Optimation as their past-cone record, exactly as we read the Cretaceous. The carryover between the two is therefore smooth by construction rather than by coincidence, and a Route World contains no moment at which one regime hands over to another.

Remark 7.14 (The symmetry with the companion, and what the corpus is). One structural fact should be stated in this work rather than left for a reader to assemble, since it is what tells the reader what the corpus *is* rather than what either paper is. The companion's inference about the deep past rests on a single licence: that an unread past outcome is a blank entry, and blanks lack tense, so that a past fluke is open to inference at all [5, 21]. The companion calls that its foundational rung, without which no inference about a past attribute can be drawn. The present work's conditioning on a future event rests on exactly the same licence: a future outcome is a blank entry, blanks lack tense, so a future-cone attribute is open to conditioning in the same sense a past-cone one is (Remark 4.19, and Remark 7.2 for the strong form).

So the two developments are one move run in opposite temporal directions on one ontology. The companion reads backward from an observer to the flukes that produced it; this work reads forward from a conditioning event to the flukes it requires; and the principle that makes either reading legitimate is the same principle in both. That is not a coincidence of two papers written by one hand. It is a fact about the ontology, and it is why the Golden Point is not an extension of Nexic reasoning but its mirror image — the same lens turned the other way. The companion's forward pointer to this work, when it is written, should be built on that symmetry and on the finding of §5.3: observer-conditioning is exactly right for the pre-technological record and provably insufficient beyond it, and a target not indifferent to the technological character of the record recovers the companion's weighting as its past-cone shadow.

Definition 7.15 (Golden causality)**.** *Golden causality* names the pattern in which an event in the moving present is accounted for by Golden Optimation, by the Aethus's conditioning on the Golden Point, rather than by the Cosmic Nexus's own rates.

The name is admissible for a reason internal to the framework rather than by indulgence. Causal talk here is not talk of a primitive relation of production: this work's causal vocabulary labels patterns of conditioning and dependence in the Aethic structure and takes no position on any further relation underneath, because the framework posits none. Where causation is not fundamental, a *kind* of causation is a kind of conditioning pattern, and Golden causality is one — named, and carrying no more than Theorem 3.2 licenses. What the name must not smuggle is the register Remark 6.11 forbids: no event pursues the Golden Point, and Golden causality describes what accounts for something, never what something is for.

Remark 7.16 (Invested Golden causality, as phenomenology). One element of the phenomenology deserves its name here, because it is the form in which Golden causality is most naturally read off a record from inside: the register of *investment*, "look how much the conditioning invested in this; it must have been necessary." The register is earned rather than decorative: the retrocausal-accordance material set aside for a further paper is its exact content, an observed route's improbability lower-bounding what it accomplished at a stated exceedance confidence,

and the retrocausal-accordance material set aside for a further paper is why the economic vocabulary of the decision-theoretic material of the broader program, set aside here was built to carry it, Aurutance's two terms are the cost and the necessity, and the investment reading is the decision rule run backward. What the register must never smuggle is agency: nothing takes the cheaper route or declines it (the retrocausal-accordance material set aside for a further paper), and the expenditure is the conditioning's concentration of weight, never anyone's spending. A Route World is, in this register, a world whose record reads as heavily and legibly invested — and §7.5 is where the temptation to read particular centuries that way is disciplined.

Remark 7.17 (The future-conditioned tradition, placed). The Strong reading has a published ancestry, and the placement discipline owes it a paragraph: Barrow and Tipler's Final Anthropic Principle [22], Tipler's Omega Point program [23], Leslie's axiarchism [24], and, ancestrally, Teilhard [25] — the branch of the anthropic tradition that conditions on the *future*, which is the branch this work lives on (the companion engages the tradition's observer-conditioning trunk; the future-conditioning branch is placed here). The deltas are real and they all cut one way. The conditioning of this work is a *measure operation*, not a dynamics: no agent at any grade, no attractor, no physical boundary condition — where the Omega program is a physical eschatology with cosmological commitments, several since falsified. This work carries published falsifiers and an epistemic ceiling that *forbids* the certified-salvation register the Omega program embraced (Theorem 3.6); and it is severable, under Void the mathematics and the critique stand with nothing conditioned on, where the tradition's packages fall whole. The delta that flatters neither side: this framework purchases strictly less, no resurrection mechanics, no convergence guarantee, no collective eschatology, and prices what it does purchase.

7.3 The empirical signature, and its limits

Two things about the credence being computed here should be fixed before the computation, since they determine what the computation is a computation *of*. *The credence is methodological, and it is a superposition.* A reasoner in a Route World holds the Golden Point as a stated attribute — that is what the hypothesis says of their Aethus. But the reasoner's *credence* that they are in a Route World is computed from less than their Aethus contains, since it is computed from the evidence accessible to them and not from the stated attribute itself. So the credence is an Aethic disagreeing superposition: the Strong hypothesis's determinate conditioning, the Golden Axiom, weighed against a Weak-type alternative in which the Golden Point is only weighted. The distinction is between methodological credence — what the evidence supports — and ontological credence — what one's Aethus in fact carries — and everything below is about the first, and never asserts the second.

The procedure does not force the conclusion. What it establishes, if the flukes keep arriving, is that each next event acts *as if* the Golden Point were being conditioned on, to whatever precision the accumulated evidence supports. That is the whole of the method's ambition, and it is the correct one: a reasoner genuinely in a Route World tends toward the conditioning by this route with arbitrarily high credence, and never reaches it, and the ceiling of Theorem 3.6 is why the second clause is not a defect.

The Route World is testable in principle, and the form the test takes is the subsubsection's main result.

Proposition 7.18 (Credence accumulation; **[P]** given the premises)**.** *Let E be the conjunction of fluke attributes observed over an interval of Aethic time, with $q = \mathbb{P}(E)$ their weight under*

the unconditioned law and $Q(E) \approx 1$ under the survivorship-conditioned law because the target requires them. The comparison is between measures, not between G and $\neg G$, since in the critical regime conditioning on G as an event does not exist:

$$\mathrm{BF}_{Q:\mathbb{P}}(E) = \frac{Q(E)}{\mathbb{P}(E)} \;\approx\; \frac{1}{q}, \qquad \textit{so} \qquad \log\text{-}\textit{evidence} \;\approx\; -\log q. \tag{14}$$

For finite information $\mathcal{F}_t$ the factor is the density itself, $\mathrm{BF}_t = dQ|_{\mathcal{F}_t}/d\mathbb{P}|_{\mathcal{F}_t}$, written generically as Z_t; in the hard-wall model of Section 3 it is the Doob density the Doob density of [2], Q^{hard}, proved, while the physically intended soft law Q^{soft} has density $e^{-\int_0^t q}\, g(X_t)/g(X_0)$ conditional on Ansatz B of [2], and every result below that consumes the density says which of the two it uses: the realized log-evidence is $\ell_t = \log \mathfrak{h}(X_t) - \log \mathfrak{h}(X_0)$, and the historical Bayes-factor argument and the stochastic $\mathfrak{h}$-transform are one object. The realized ℓ_t is the logarithm of a $\mathbb{P}$-martingale and fluctuates along a path; what rises is its Q-expectation, the information of the information coordinate of [1].

Three things follow, and the second is the one that keeps the procedure honest. *The evidence is the same object the decision-theoretic material of the broader program, set aside here computes.* $\mathfrak{h}$ is what the Golden Score is a ratio of (the Golden Score of the broader program, set aside here), so the Route World's credence and the decision rule consume one quantity, and both wait on the same missing map (the identification map, an open problem of the broader program). *And that map is what stops the procedure being unfalsifiable.* Absent it, "what counts as a fluke" is chosen after the fact, and a sufficiently motivated observer finds flukes anywhere — the look-elsewhere problem, which would make (14) an instrument for confirming whatever it was pointed at. With it, a fluke is whatever raises $\mathfrak{h}$, which the model fixes and the observer does not. The methodology's rigor is therefore hostage to the identification map, an open problem of the broader program's open problem, and should be described that way rather than advertised as available.

The aggregate does not determine its own decomposition, and identifiability is a matter of degree. The likelihood ratio is a function of the *state*, $\mathfrak{h}(X_t)/\mathfrak{h}(X_0)$, and not a ledger of which happenings supplied it: an accumulated 20 nats, a Bayes factor near 5×10^8, is equally the signature of one unmistakable event, of two hundred each amounting to a ten-percent tilt, or of two thousand at one percent apiece, and the aggregate does not distinguish the cases.

It does not follow that no individual event is identifiable, and the qualification matters. A happening of conspicuously low weight under the Cosmic Nexus is exactly the case Theorem 3.2 speaks to: its update factor on futures is correspondingly large, so a future accounting for it is favored in the stated ratio, and the principle is thereby the *detection instrument* for such events rather than merely a constraint on them. Large single contributions can be found, and an observer who knows to look will find some.

What resists is the rest, and the shape of the resistance is steep. Writing θ for the weight at which a single event becomes conspicuous and μ for the typical contribution, the share of total evidence residing in conspicuous events falls like $e^{-\theta/\mu}$: at θ a twenty-to-one improbability and a total of 20 nats, three large events put ninety-two percent of the evidence in plain sight, twenty events put twenty percent, and two hundred put none.[7] And under the log-spread laws this work uses elsewhere, (the technoanatomy companion [3]), the two quantities that matter come apart: with contributions lognormal at spread 3 over two hundred events, roughly *one*

[7] Exponential contribution sizes at fixed mean, for which the conspicuous share is $(1 + \theta/\mu)e^{-\theta/\mu}$ exactly.

carries sixty-three percent of the evidence. A handful is findable, those few are decisive, and the proportion of contributing events they represent is under one percent.

So the accurate statement is that a Route World should be expected to leave a few conspicuous traces and a great many invisible ones, the conspicuous few carrying a large share of the evidence and a negligible share of the count. Evidential dominance and numerical proportion are different quantities, exactly as the technoanatomy companion [3] finds them for orderings, and an observer who located every conspicuous trace would still not have located most of what happened. That is the broader Golden program, set aside here's class-versus-instance discipline arriving from the evidential side.

Three tasks are worth separating here, because the paragraph above runs two of them together and the third is the one with a future. *Detecting* the aggregate needs no localization whatever: (14) reads the accumulated ratio off the state, and two hundred invisible ten-percent tilts deliver the same decisive 5×10^8 as one conspicuous event would. *Localizing the tail* is what Theorem 3.2 does. *Localizing the bulk* has no instrument at all, and the reason is specific: the accordance principle is a *marginal* test, it interrogates one attribute's weight under the Cosmic Nexus and infers from that weight alone, so an event contributing at a magnitude no marginal test resolves is invisible *to it*, which is a fact about the instrument and not about the event.

That distinction leaves room, and the room should be marked rather than conceded. The accordance principle is the elementary instrument here: it requires only a weight and a comparison, it is available immediately, and it is correspondingly coarse. Nothing establishes that it is the best available in principle. What a finer instrument would have to do is compute an event's contribution to $\mathfrak{h}$ *without routing through that event's marginal improbability* — and an instrument of that description is not hypothetical, it is the identification map, an open problem of the broader program's missing identification map, which is exactly a rule assigning states to events by their own structure rather than by their rarity. The Route World therefore acquires the same open problem the decision-theoretic material of the broader program, set aside here has, from the other direction, and a second reason to want it solved: the map would convert localization from a tail-only capability into a general one. Until then, the coarse instrument is what there is, and the estimate that a handful of traces is findable while the bulk is not should be read as an estimate about present instruments rather than a claim about what a Route World conceals [**O**].

Remark 7.19 (The attribution is lost in the representation, not in the world). It is worth being exact about where the localization problem comes from, because the answer says what a better instrument would have to do rather than merely that one is wanted. The Aethic object is a structure: attributes standing in dependency relations, with weights over the fan. The model of Section 3 projects that structure onto a scalar, a hazard, and downstream a single harmonic value, and the projection is many-to-one by a wide margin. *The attribution information is discarded at the projection.* Nothing about the world hides which events contributed; the representation this work computes in does not carry the answer, because a number cannot. That is why the identification map is hard: it is an inverse to a projection that discarded what the inverse needs, and inverses of that kind are recovered by supplying structure rather than by supplying data.

It also says what the accordance principle is finding. A marginal test on weights locates the attributes of high dependency degree, the ones on which much else turns, and which are correspondingly improbable in isolation, so what the principle recovers is a *skeleton*: the trunk and the hubs of the dependency graph, and not its edges. Working in the unflattened structure would

be working with the graph rather than its scalar summary, and there the bulk contributions are not small numbers lost in an aggregate but edges with endpoints. Whether the framework's dependency structure supports inference at that grain, and what volume of recorded attribute-data would make the closure computable, is open, and is a different open problem from the identification map rather than the same one [**O**].

Remark 7.20 (The collapse condition is also a legibility condition). One consequence runs the other way and bears on the companion rather than on this work. The companion's collapse condition, $c_{\text{eff}} > \log_{10}(n(b-1))$, is stated as a fact about *weight*: above it, the realized ordering carries a share of order unity. It is equally a fact about *inference*, and the second reading has not been drawn.

Take the effective number of live alternatives to be the exponential of the entropy over the tier structure. At twenty interrogable slots of ten values the nominal space is 10^{20}; at c_{eff} just above the threshold it is a few hundred; at $c_{\text{eff}} = 3$ it is four; and by $c_{\text{eff}} = 5$ it is one to within a percent. The collapse is sharp, and what collapses is the space a reconstruction must search. So the same contrast that makes the record improbable makes it *legible*: reconstruction of a high-contrast natural history requires data scaling with the surviving handful rather than with the nominal branching, which is the precise content of the intuition that knowledge here should grow quickly once methods are good enough to exploit the concentration. The threshold such methods must reach is the collapse condition itself.

Two cautions. The concentration is *conditional*, it is what the conditioning purchases, and without it the space is the nominal one, so the legibility cannot be cited as unconditional evidence for the conditioning without circularity. And concentration is not determinism: one ordering carrying a share of order unity leaves the others weighted rather than excluded, and Definition 4.11's grading is exactly the difference. What is available honestly is a prediction: if the conditioning holds, reconstructions of deep history should converge on less evidence than a flat-prior analysis of the same branching would require, and that is checkable without any fluke being counted [**O**].

One further consequence cuts against the methodology's own convenience. How large the required flukes are depends on how much work the conditioning has to do: a position from which the Golden Point is already comparatively likely requires only small corrections, while deep time, from which it was not, required the large ones the hypothesis assigns to the record. A biosphere improving its position should therefore expect its Golden-Optimation events to grow *less* conspicuous, so the evidence available to (14) thins exactly as the situation it reports on improves, and the method is at its most informative where the news is worst [**O**].

The ceiling permits the ambition and forbids the conclusion. By Theorem 3.6 the two measures are mutually absolutely continuous on every finite window and singular only on the infinite-horizon σ-algebra, so the likelihood ratio is finite at every finite time: credence may rise without bound and *never certifies*. That is not a limitation discovered here but the theorem's own shape, and it is the exact sense in which the procedure can approach the conclusion asymptotically while being barred from reaching it.

7.4 What would distinguish the three worlds

A hypothesis with a phenomenology owes a statement of what would tell it from its rivals, and this is where the Route World's status is decided. The answer has two halves and they point in opposite directions.

What differs. The three worlds make different predictions about the *rate* at which an observer encounters improbabilities against the Cosmic Nexus's own rates.

Void. Nothing constrains the forward cone, so improbabilities arrive at the Cosmic rate: after one's present, flukes are as rare as the unconditioned weighting says, and Optimation is a fact about the record only, and the realized log-likelihood favors $\mathbb{P}$ in expectation: $\gamma_{\mathbb{P}} < 0$. *Weak.* The forward cone is weighted by Golden-Point probability, so improbabilities arrive at a rate above Cosmic and below what full conditioning gives — and, since Weak's anchor does real work, at a rate depending on one's position. No rate prediction exists for Weak until its law is specified: a partial-conditioning family R_θ, a tempered Doob transform, or a finite-horizon conditioning regime, with $\gamma(\theta) = \lim_t \mathbb{E}_{R_\theta}[\ell_t]/t$ computed and the ordering $\gamma(0) < \gamma(\theta) < \gamma(1)$ proved, which is open **[O]**.

Strong. The conditioning is resolved throughout the cone, the Golden Axiom holding (Axiom 1), so required improbabilities arrive at the full conditioned rate, and by Proposition 7.18 the realized log-likelihood favors Q in expectation at the Q-expected rate, $\gamma_Q = \lim I_t/t > 0$, while ℓ_t fluctuates about its mean. The discriminating quantity is therefore the sign of the expected log-likelihood growth under the actual law: Void and Strong predict opposite signs for the Q:$\mathbb{P}$ log-evidence under their own generating laws, and Weak awaits its law. Two things bear on reading it. Remark 7.13 says the label attaching to any given fluke is tense-relative, so an observer cannot distinguish the worlds by inspecting individual events; only the *rate* discriminates. And by the identifiability analysis of §7.3, the rate must be read from the aggregate $\mathcal{L}_t$ rather than from a ledger of attributed events, since the aggregate does not decompose. What one compares is a log-likelihood ratio against a Cosmic-rate baseline: Void predicts that it falls in expectation, at the rate $-D(\mathbb{P}\|Q)$, and Strong that it grows.

What does not. By Theorem 3.6, Q and $\mathbb{P}$ are mutually absolutely continuous on every finite window and singular only on the infinite-horizon σ-algebra. So the discriminating quantity is finite at every finite time. Evidence for Strong can accumulate without bound and never certify; evidence for Void can only ever be the absence of accumulation, which is compatible with Weak at low flux and with Strong at early time. *No observation of bounded duration decides among the three.*

That is not a limitation the Route World discovers about itself but the ceiling's own shape, and it should be read as the point rather than as a disappointment. What the framework predicts is a *trend*, a log-likelihood ratio that rises in expectation under Strong and falls in expectation under Void, Weak having no rate prediction until an explicit intermediate law is supplied, and a trend is exactly the kind of prediction that accumulates credence without converting to certainty. A reader who wants a decisive test is asking for something the framework proves it cannot supply; a reader who wants a discriminating quantity has one.

The scoring. The Route World therefore has a phenomenology, a discriminating quantity, and no decisive test — and the last is a theorem. That is a weaker empirical status than a falsifiable prediction and a stronger one than a metaphysical hypothesis with no observational content, which is where Strong stood before this section. What the section has done is move Strong from the second category into the first, and no further.

Remark 7.21 (Prepositioned prerequisites: a second discriminating quantity, physical rather than historical; **[S]** with an open specification problem). The flux is a historical quantity, read from the record of events that have already occurred. The author proposes a second discriminating

quantity of a different kind, read from physical structure that has not yet been used. Suppose the route to the Golden Point requires resources this planetary system either has or lacks, of the sort a departure from the system would consume, and suppose those resources are not required for anything that has happened so far. Under the strong reading the conditioning is resolved throughout the cone and the route is realized, so whatever the route needs must be in place; the requirement is therefore already satisfied in structure standing today and available for inspection, well before anyone consumes it. The author's illustrative case is water ice in outer-system locations that later turn out to matter, and the example is illustrative only, carrying no weight of its own.

The reason this quantity is worth stating separately is that it escapes the blur that limits the first. Remark 7.13 observes that the label attached to any individual fluke is tense-relative, so an observer cannot sort worlds by inspecting events, only rates. An *unconsumed* prerequisite is the one class of feature to which that objection does not apply, because nothing in the past has used it: it cannot have been observer-necessary, having so far been necessary for nothing at all. This makes prepositioning a genuine discriminator between the readings rather than a further instance of the same evidence, since observer conditioning constrains only what the past required, and says nothing whatever about what the future will need. Two things must be controlled before the discrimination is real. The resource must not be a byproduct of the same processes that produced habitability, which is the common-cause confound, and the base rate must be computed conditional on habitability so that observer selection is not doing the work unnoticed. With those controls the evidential structure is exactly that of Proposition 5.3: the likelihood ratio is one over the probability that an arbitrary habitable system satisfies the stated requirements, and the force of the test is the smallness of that probability, which comparative planetology may eventually estimate as the census of systems grows. The falsifier follows directly. If our system's provisioning against requirements specified in advance turns out median or worse among habitable systems, that counts against the strong reading rather than for it.

The specification problem is the honest catch, and it is the author's own. The test has force only when the requirement is fixed before the provisioning is inspected, or the retrospective-target null of Remark 5.6 consumes it entirely, and fixing the requirement demands joint knowledge of what the route will need and of what supplies it, which a species at our epistemic stage does not have. The conservative form of the claim is therefore addressed to descendants rather than to us: as the epistemology of Golden-Point necessity matures, prerequisites should be found to have been visible in the physical record long before their necessity was understood, so that the sentence available to our descendants is that a feature already lay open to our inspection and turned out to be required. That is a prediction about a future epistemic state, scoreable by those who reach it and not by us, and it is entered at the same grade and with the same honesty as the reception-scale predictions of the decision-theoretic material of the broader program, set aside here. The ceiling governs throughout, since a satisfied requirement raises the ratio and certifies nothing.

7.5 Why the historical cases do not discriminate

A reader who accepts the previous subsection's discriminating quantity will nonetheless want to reach for something nearer to hand, and the material is genuinely there: read a consequential century closely and what had to go right is startling. This subsection says what such cases do and do not support, because the temptation to over-read them is strong and the framework's own guards are what keep the reading honest.

The material. If one is in a Route World then one has been in it throughout, and any century should show it. The scientific enlightenment is the case most often reached for, and it repays the reach: the transmission of algebra; the printing press and the literate market it made [26], and — less often noticed and more interesting — a theological temperament under which fitting exact laws to the world was a natural thing to attempt rather than an eccentric one — a standing thesis of the historiography [27]. Counterfactuals of the usual shape suggest themselves. Had Rome persisted in a form that left no room for the religious configuration that followed, it is not obvious that the temperament distinguishing Renaissance mathematics from Archimedean mathematics would have arisen; and the material prerequisites have their own contingencies, paper among them. Each century then sets conditions for the next, which is the schedule structure of the schedule of [3] in a documentary register: gates in order, with the ordering doing work.

What they support. The cases are the human-history leg's own material (§5.3), and what they support is what that leg argues: that the conditioning is sensitive to the technological character of the record, which observer-conditioning is not. That is a claim about *which target*, and these cases bear on it.

What they do not. They are past-cone cases, and the distinction that matters is exactly the one Definition 7.12 draws. A fluke already in the record is *consistent with* Golden Optimation and is equally consistent with ordinary Optimation — the conditioning event behind one, the supply bounded by what has happened. By Remark 7.13 the label attaching to any past fluke is tense-relative, and a fluke that lies behind an observer carries no information about whether the conditioning extends ahead of them. So historical cases are *Past-Alignment consistent*, which is the milder claim, and they do not discriminate Strong from Weak or from Void. Only the flux does, and the flux is a rate in the observer's forward cone.

The stronger phrasing, *documentable cases of Golden causality*, should accordingly be resisted. By Definition 7.15 Golden causality names events accounted for by the Golden conditioning *rather than* by Cosmic rates, and establishing that of a particular event requires establishing the conditioning, which is what is at issue. What is documentable is consistency, and consistency with a hypothesis is not evidence for it over a rival the same data also fit.

Remark 7.22 (Three guards, and the one that bites hardest). The historical material is where this work's own cautions apply with most force, and they should be applied before the material is used rather than after it is challenged.

The scan is enormous. The exceedance form's multiplicity guard (Definition 3.1) bounds expected κ-fold violations among n interrogated pairs by $n/(1+\kappa)$, with the standing condition that n counts attributes *scanned* and not merely those interrogated. For a century read by historians, the scan is every attribute anyone has ever found notable, and an honest n is enormous. The noise floor is correspondingly high, and a historical trace must stand clear of it by a wide margin before it is worth anything. This is the guard that bites hardest and it is the one most easily skipped.

Substitution is the question, not occurrence. §5.3 audits by *role* and not by occupant: the question is never whether Christianity in particular arose, but whether anything arose that discharged the role. Applied to the temperament case this cuts both ways, and interestingly. Material prerequisites look substitutable — many routes lead to mass literacy, and the printing press is one occupant of that role. A specific epistemic disposition looks less so, since it is not

obvious what else would have discharged it; and if that holds, temperament is a *serial* attribute in the sense of Remark 6.8 where the technology is parallel, and contributes correspondingly more to R_1. That is a conjecture about substitutability and not a finding, and it is exactly the kind of claim the serial-attribute programme exists to settle **[O]**.

And narrative bias is prior. Remark 5.8 states the objection and the asymmetry that answers it, and nothing in this subsection escapes it: dramatic near-misses make better stories and are more often recorded, so a century dense with them may be reporting a fact about historiography. The test remains the connectivity asymmetry that remark names, and no accumulation of vivid cases substitutes for it.

8 The Paradox of Departures

The empirical consideration at the center of Golden reasoning is that our biosphere stands just short of the Golden Point: among the nameable variations of ourselves we hold the highest disposition toward reaching it (the pinnacle invariant, (7)), and on the Strong hypothesis's own chronology we stand some centuries short of the event. Our forward weight therefore splits in two. With some probability the biosphere takes the full boost of Remark 7.6, the climb completed and the Golden Point reached; with the rest it takes no boost at all, and stands in the non-reaching class beside the histories of high biological entropy that hold almost all of that class's weight.

The author calls the following thought experiment the *Paradox of Departures*. Suppose the second branch is the one that comes to pass: one's biosphere departs short of the Golden Point, by an impact or another hazard from space or by any other route, so that one's Aethus comes to be a departing one by virtue of the departure's actually happening. One's future Aethae are one's own once they arrive, and warrant the first postulate on one's behalf. The departing Aethus would therefore occupy the target seat H^+ of the Accordance chain (§5.1.2), the seat the Golden Aethus fills in the Route World, the supposition itself supplying the chain condition (Remark 5.2), and scoping it for inhabitability (Definition 3.7) applies to one's present with it as the target. The present fails the scoping, by a fluke whose size the record fixes, and the argument is by contradiction: to the confidence the principle carries, one does not come to occupy such an Aethus, so the non-Golden alternative does not come to pass and the Golden Axiom holds of us. The paradox has two forms. The *general form* prices a departure against the whole of the exotic structure Nexic reasoning logs in our record; the *external form* prices it against the external channel's exponential hazard, where the fluke can be computed outright. The section records the author's argument and does not adjudicate it.

Definition 8.1 (Departing Aethae)**.** A *departing Aethus* is an Aethus in which one's biosphere departs short of the Golden Point: some survival attribute of Definition 7.3 fails at a finite proper time, so that the Aethus is disjoint from $\mathfrak{G}$ and the Golden Axiom fails of it. For a window of length ℓ opening at one's birth, which falls at elapsed time $\tau_{\oplus}$ in the biosphere's record, the *external departing Aethus* $\mathfrak{D}_\ell$ is the departing Aethus in which the departure falls within the window and is made by the external channel, the background an incomplete schedule leaves unshielded [3]: an impact or another hazard from space, a departure-sufficient occurrence of the kind the record shows.

The general form. For this form the author reads the Golden Point as the successful lowering of the total hazard of departure: the hazard of μG, the whole stochastic object whose external

and internal channels (Definition 3.4) price the mechanisms (Remark 4.3) and whose excess the technoanatomy companion's schedule channel first estimates [3], lowered at the center about which it fluctuates. On that reading the non-reaching class is the class whose total hazard keeps its floor, and Theorem 3.8 is why its share falls toward zero under survival conditioning, however small the drop and however rare the structure that buys it. Let E be the record's exotic structure: the improbabilities Nexic reasoning logs in our record and Golden reasoning reads as the climb's prerequisites, the evidence of Principle 3 in human and in natural history alike (§§5.3 and 6.1). It is the structure on which one's living until now definitionally relies, and its Cosmic-Nexus weight is extremely low: at most the q of (8) and (14), which the weight bound of §6.1.1 estimates and which, for a predeclared family of route-deleting flukes, is at most the product of their weights (Proposition 5.4). A departing future takes none of that structure as a prerequisite and returns nothing on it. An incomplete schedule leaves the biosphere at bare background, so departing histories carry exotic structure at its bare weight, and the departing class, which holds nearly all of the Cosmic Nexus's weight, is held overwhelmingly by histories of high biological entropy, a barren Earth from the beginning the limiting case (Remark 7.6). Relative to a departing future the record is therefore a fluke of the size of its own weight, the sliver of the non-reaching class that carries the structure, against the entropic slush that holds the rest; and scoping the departing future with E as the realized present caps its weight at that size:

$$\mathrm{cr}(\text{departing}) \;\lesssim\; \iota(\text{departing}) = \mathbb{P}(E \mid \text{departing}) \;\le\; \frac{q}{\mathbb{P}(\text{departing})} \;\approx\; q, \tag{15}$$

with $\lesssim$ the exceedance modality of Theorem 3.2, the middle step because $\mathbb{P}(E) \le q$ and the last because the departing class holds nearly all of the weight. The Golden and Departure Points being complements on definite states (Remark 4.2, [**P**]), the Golden Point carries the weight the cap leaves, at least $1 - q$ to the principle's confidence. The rarer the record, the tighter the cap: on this form of the paradox, the improbability Nexic reasoning finds in our past measures how improbable it is that we depart.

The fluke can be moved between two places and is not removed by moving it. Under the observer-conditioned law H_O of Principle 3 the record is the fluke, at weight q; under the Golden-conditioned law H_G the departure is, a law conditioned on the Golden Point giving departure no weight. Any mixture of the two laws therefore gives the record together with a departure a probability of at most q, which is the general form's counterpart of the frontier bound of Proposition 8.2. Granted H_G outright, the reading the author first gave the argument, a departure is a fluke twice over: at every finite horizon the non-reaching class's share of the conditioned weight falls toward zero (the survival-time threshold [3], and for any fractional drop (3)), and within that class the histories carrying our exotic structure hold a share of order q, the rest being the high-entropy histories the structure does nothing to outlast.

The external form. Take the departure to be $\mathfrak{D}_\ell$, made by the external channel within one's own lifetime. If the external rate is low, the departure's falling within one's lifetime is the fluke; if it is high, one's having been born this late is the fluke, since a departure at the rate the lifetime suggests would have come early in the record, and anyone whose lifetime held it would have lived far earlier. On the author's reading the departure is a point sample: with the clock started at one's birth, it is one exponential waiting time $w \le \ell$, which on its own places the rate near $1/w$, a one-observation interval at 95 per cent running from about $0.025/w$ to $3.7/w$; at any rate in that interval the lateness factor is below $e^{-0.025\,\tau_\oplus/\ell}$, about $10^{-4.4\times10^5}$ for a record of four billion years and a lifetime of a century. Fixing the rate makes either horn mediocre, and

the other then carries the whole fluke. The *bi-distribution* below is the author's construction in place of that axial reading: the joint law of the two axes, lateness and window, under every rate at once.

Proposition 8.2 (The external form: the bi-distribution; **[P]** given the model)**.** *Let external departures arrive at a constant rate $\lambda \geq 0$ from the biosphere's origin, independently of the record, so that the first departure time D is exponential with rate λ ($D = \infty$ at $\lambda = 0$); let one's birth fall at elapsed time $\tau_\oplus$ and the window have length ℓ. Then:*

(i) The two axes. *The probability that the record runs late enough to hold one's birth and that the departure then falls within the window factors, the clock restarting at one's birth by the memorylessness of the exponential:*

$$J(\lambda) \;:=\; \mathbb{P}_\lambda\big(\tau_\oplus < D \leq \tau_\oplus + \ell\big) \;=\; \underbrace{e^{-\lambda\tau_\oplus}}_{\textit{lateness}}\,\underbrace{\big(1 - e^{-\lambda\ell}\big)}_{\textit{window}}. \tag{16}$$

Each rate places the configuration at the point $(x, y) = (e^{-\lambda\tau_\oplus},\, 1 - e^{-\lambda\ell})$ of the unit square, the probabilities of its two halves, and as λ runs over $(0, \infty)$ the point traces the frontier *$y = 1 - x^{\ell/\tau_\oplus}$. The frontier, with any weighting of rates as a distribution on it, is the bi-distribution, and $J = xy$.*

(ii) The joint bound. *J has a unique maximum, at $\lambda_* = \ell^{-1}\log(1 + \ell/\tau_\oplus)$, which is $1/\tau_\oplus$ to within a factor $1 + O(\ell/\tau_\oplus)$, and*

$$\sup_{\lambda \geq 0} J(\lambda) \;=\; \frac{\ell}{\tau_\oplus}\Big(1 + \frac{\ell}{\tau_\oplus}\Big)^{-(1+\tau_\oplus/\ell)} \;<\; \frac{\ell}{e\,\tau_\oplus}\,: \tag{17}$$

the frontier lies wholly below the hyperbola $xy = \ell/(e\tau_\oplus)$, meeting it nowhere and approaching it, at $x = 1/e$, as $\ell/\tau_\oplus \to 0$.

(iii) The axial readings. *Mediocre lateness, $x = \frac{1}{2}$, puts the rate at $\ln 2/\tau_\oplus$ and the window factor below $(\ln 2)\,\ell/\tau_\oplus$; a mediocre window, $y = \frac{1}{2}$, puts the rate at $\ln 2/\ell$ and the lateness factor at $2^{-\tau_\oplus/\ell}$. At every rate $\lambda \geq 1/\ell$, where a departure within the window is no fluke, $J(\lambda) \leq e^{-\tau_\oplus/\ell}$.*

(iv) Mixtures. *For any weighting π of rates, $\int J\,d\pi < \ell/(e\tau_\oplus)$. For the scale-free weighting, uniform in $\log\lambda$ on $[\lambda_-, \lambda_+]$,*

$$\int J\,d\pi \;\leq\; \frac{\log(1 + \ell/\tau_\oplus)}{\log(\lambda_+/\lambda_-)}, \tag{18}$$

with near-equality when $\lambda_-\tau_\oplus \ll 1 \ll \lambda_+\tau_\oplus$.

Proof. (i) $\mathbb{P}_\lambda(D > \tau_\oplus) = e^{-\lambda\tau_\oplus}$, and by memorylessness $\mathbb{P}_\lambda(D \leq \tau_\oplus + \ell \mid D > \tau_\oplus) = \mathbb{P}_\lambda(D \leq \ell) = 1 - e^{-\lambda\ell}$; eliminating λ between the coordinates gives the frontier. (ii) $J(\lambda) = e^{-\lambda\tau_\oplus} - e^{-\lambda(\tau_\oplus+\ell)}$ vanishes at 0 and as $\lambda \to \infty$, and $J'(\lambda) = e^{-\lambda\tau_\oplus}\big[(\tau_\oplus + \ell)e^{-\lambda\ell} - \tau_\oplus\big]$ changes sign once, where $e^{\lambda\ell} = 1 + \ell/\tau_\oplus$. With $r = \ell/\tau_\oplus$, there $e^{-\lambda_*\tau_\oplus} = (1 + r)^{-1/r}$ and $1 - e^{-\lambda_*\ell} = r/(1 + r)$, whose product is the middle expression, and $\lambda_*\tau_\oplus = \log(1+r)/r = 1 - r/2 + O(r^2)$. The strict inequality is $(1 + 1/r)\log(1 + r) > 1$, that is $\log(1 + r) > r/(1 + r)$, which holds for every $r > 0$; the ratio of the two sides tends to one as $r \to 0$, with $x = (1 + r)^{-1/r} \to 1/e$. (iii) Direct substitution, with $1 - 2^{-r} < r\ln 2$; and for $\lambda \geq 1/\ell$, $J(\lambda) \leq e^{-\lambda\tau_\oplus} \leq e^{-\tau_\oplus/\ell}$. (iv) The first statement is (ii)

reading	$1/\lambda$ (years)	lateness $e^{-\lambda\tau_\oplus}$	window $1-e^{-\lambda\ell}$	joint J
	4×10^{11}	0.990	2.5×10^{-10}	2.5×10^{-10}
	4×10^{10}	0.905	2.5×10^{-9}	2.3×10^{-9}
mediocre lateness	5.8×10^{9}	0.500	1.7×10^{-8}	8.7×10^{-9}
joint maximum	4.0×10^{9}	0.368	2.5×10^{-8}	9.2×10^{-9}
	4×10^{8}	4.5×10^{-5}	2.5×10^{-7}	1.1×10^{-11}
	4×10^{7}	3.7×10^{-44}	2.5×10^{-6}	9.3×10^{-50}
	4×10^{5}	1.1×10^{-4343}	2.5×10^{-4}	2.8×10^{-4347}
	4×10^{3}	3.3×10^{-434295}	0.025	8.1×10^{-434297}
mediocre window	144	$10^{-1.20\times10^7}$	0.500	$10^{-1.20\times10^7}$
	100	$10^{-1.74\times10^7}$	0.632	$10^{-1.74\times10^7}$

Table 1: The frontier of Proposition 8.2 at the scale of our record, $\tau_\oplus = 4\times10^9$ years and $\ell = 10^2$ years, one row per external rate, given by its mean interval $1/\lambda$. The joint never exceeds $\ell/(e\tau_\oplus) \approx 9.2\times10^{-9}$, and its maximum sits at the low-rate end, where lateness is near mediocre and the window carries the fluke; every rate at which a departure within a lifetime is unremarkable pays for it in lateness.

integrated against π. For the second, $d\pi = d\lambda/\big(\lambda\log(\lambda_+/\lambda_-)\big)$ on the range and $J>0$, so the integral is at most $\int_0^\infty \big(e^{-\lambda\tau_\oplus} - e^{-\lambda(\tau_\oplus+\ell)}\big)\,d\lambda/\lambda = \log\big((\tau_\oplus+\ell)/\tau_\oplus\big)$, Frullani's integral, divided by $\log(\lambda_+/\lambda_-)$. Since $J(\lambda)/\lambda \le \min(\ell, 1/\lambda)\,e^{-\lambda\tau_\oplus}$, the parts of Frullani's integral outside the range are at most $\ell\lambda_-$ below it and $(\ell/\tau_\oplus)e^{-\lambda_+\tau_\oplus}$ above it, against a total near $\ell/\tau_\oplus$. □

At the scale of our record, with $\tau_\oplus \approx 4\times10^9$ years and a lifetime $\ell \approx 10^2$ years, so that $\ell/\tau_\oplus \approx 2.5\times10^{-8}$, Table 1 lays the frontier out. The joint maximum is 9.2×10^{-9}, at about one external departure per 4×10^9 years; mediocre lateness gives 8.7×10^{-9}; a mediocre window leaves a lateness factor near $10^{-1.2\times10^7}$. A weighting uniform in $\log\lambda$ across twenty decades centered on $1/\tau_\oplus$ brings the joint to 5.4×10^{-10}. Taking the window to be the distance still to be covered to the Golden Point rather than a lifetime, some centuries, raises these by a factor of a few: three centuries give a joint maximum of 2.8×10^{-8}, and a millennium one below 10^{-7}.

Remark 8.3 (What the bi-distribution shows that the axial readings do not). The author's two horns are the frontier's two ends, and each axial reading fixes one of them at mediocrity and charges the other with the whole fluke. The two readings disagree by some twelve million orders of magnitude, so a reading that chooses between them has chosen its answer. The bi-distribution settles the apportionment instead of choosing it. The joint is greatest in the interior, at a rate near $1/\tau_\oplus$, where the lateness factor is $1/e$ and the window carries the fluke, so the low-rate horn is very nearly the best a departing Aethus can do, and the best it can do is a fluke of one in $e\tau_\oplus/\ell$, about one in 10^8. The high-rate horn is not a competitor: every rate at which a departure within a lifetime is unremarkable costs a lateness factor below $e^{-\tau_\oplus/\ell}$. No weighting of rates escapes the bound, the joint of a mixture being the mixture of the joints, and a weighting agnostic across scales lowers the joint further, by the logarithm of the range it is agnostic over. That is the sense in which the joint probability has to be low: not by a choice of horn, but uniformly in the rate.

The general form has the same shape. The record's weight q stands where the lateness factor stands here, and a departure short of the Golden Point where the window factor does; the frontier is spanned by the two outer measures of Principle 3, and the bound is q. And the proposition takes any window and any elapsed time, so it bounds departure by any channel

whose rate has been constant since it opened, at that channel's own age. The external channel is the one whose rate has acted across the whole record, which is why the external form is posed for it, and why its bound is the tightest the record supplies.

Remark 8.4 (The Paradox of Departures, the argument by contradiction; **[S]**, the author's argument, a proposal and not an adjudication). Suppose one comes to occupy a departing Aethus. In the general form one's record is then a fluke of weight at most q relative to it (15): the sliver of the non-reaching class that carries the exotic structure on which one's living until now relies, against the entropic slush that holds the rest. In the external form, with $\mathfrak{D}_\ell$ the Aethus occupied, the record and its departure together are a fluke under every rate the external channel could have, by the factor $e\tau_\oplus/\ell$ at the least (17), about 10^8, whether the rate is low and the timing is the fluke or the rate is high and the lateness is. Either way the present would fail the scoping of the Aethus it unfolds into, and the weight of unfolding into that Aethus is constrained in proportion to its dubiousness (Definition 3.7). So, to the confidence the principle carries, one does not come to occupy a departing Aethus.

The cap prices and does not forbid, so the conclusion is a mixture and not an exclusion: the non-violating sliver keeps its weight. With c one's confidence in the principle's application to our record, ε the cap, at most q in the general form and below $\ell/(e\tau_\oplus)$ in the external, and π_0 the weight a departing Aethus would carry without the principle, one's credence in a departing Aethus is the linear combination of the two cases, which is the author's scoping of the departing Aethus for inhabitability, with ε its inhabitability,

$$\mathrm{cr}(\text{departing}) \;\lesssim\; c\,\varepsilon + (1-c)\,\pi_0, \tag{19}$$

and the remainder of the weight goes to the continuations in which the Golden Point is reached. Since a departure is the non-Golden alternative, the Golden and Departure Points being complements, the non-Golden Aethus does not come to pass, up to the mixture's residue, and one's weight-carrying continuations carry $\mathfrak{G}$ but for that residue. The author's conclusion is that the Golden Axiom holds of us: we are in the Route World (Definition 7.1), and the Strong hypothesis is true. Pushed to the asymptote, the H_G reading of the general form leaves the non-reaching class no share at all, which is the passage from the family to the measure: at every finite horizon that class keeps some weight, and in the limit its share is zero, which is the measure Q the axiom states (Remark 7.5).

It is a paradox because it runs a principle about one's past forward onto one's future, and reaches a verdict the received reading cannot: a departure that would be accidental, an impact from space indifferent to everything the record holds, is priced by the record. It is the forward counterpart of the finale paradox, which asks why one occupies the present rather than deep time and is discharged by an accounting future that takes the modern record as prerequisite; a departing future accounts for nothing in the record, and the record it would leave is the record of a fluke. At the scale of one life the inference is familiar: a standing ability that no future calls on is a fluke with respect to that future, and so is a standing climb with respect to a future in which no Golden Point completes it.

Remark 8.5 (Why the paradox is not the doomsday inference). The paradox reasons about the end of a record from one's place in it, and a reader will hear the doomsday argument in it [28]. It is that argument's opposite in verdict and its contrary in method. The doomsday inference shifts weight toward an early end by drawing one's birth rank from a completed roster whose total is a blank, a normalizer the Accordance Principle does not license, since it binds attribute by attribute and a position in a roster has no attribute-wise translation [4]. The paradox finds

an end within one's lifetime improbable, and draws no position at all. Its general form prices a stated attribute of one's record against a future, by the scoping; its external form bounds a stated configuration under every law the hazard could have, each factor of (16) the weight of an attribute that $\mathfrak{D}_\ell$ itself states, its record being complete from origin to departure. It normalizes over what is stated. Gott's Copernican estimate [29] gives an end within ℓ of a system that has lasted $\tau_\oplus$ the probability $\ell/(\tau_\oplus + \ell)$, the magnitude of (17) and larger by about e. The agreement is in magnitude and not in route: Gott's estimate draws a position uniformly from a total duration, an input justified by indifference, where the bound here is a supremum over hazard laws and draws nothing.

Remark 8.6 (What the paradox is conditional on). Three fences hold, as they hold for every argument in this paper. *The ceiling.* The paradox supplies credence and not certification: no finite observation certifies its conclusion (Theorem 3.6), the credence may rise without bound and never certify (§7.3), and the residue of (19) is the ceiling's room in the mixture. *The premises.* It consumes the scoping of Definition 3.7 at that procedure's grade, $[\Phi]$ in application to our record, with the chain condition the supposition supplies (Remark 5.2). The general form consumes the estimate of q at the grade of §6.1.1 and the no-boost property of an incomplete schedule at the technoanatomy companion's grade; the external form consumes the constant-rate model, and is **[P]** only given it. The external form's lateness factor prices one's having lasted until one's birth rather than conditioning it away, as the Accordance Principle prices a rate that would leave the production of observers improbable. Under a reading that conditions survival away, the one on which a kind rate and a survivor's luck are hypotheses the finite record cannot separate, the anthropic shadow [30], the high-rate horn goes unpriced and the external form rests on the weighting of rates; the general form, whose fluke is the record's content and not its length, is untouched. *The record.* The argument is the author's, recorded as his beside the three hypotheses. It decides nothing on the reader's behalf, and the section that develops the Route World (Section 7) continues to describe that world rather than argue for it.

9 What is not claimed

9.1 Fences

Remark 9.1 (Determinate is not accessible, and why the distinction cannot be relaxed here). An objection is available against the fences below, and it is good enough that stating it is better than hoping no reader finds it. It runs as a model comparison. *The objection.* The fences say that whether one's own contribution is among the conditioning's requirements is a thing no observer can establish. But the Route World is precisely the hypothesis that the conditioning is *resolved* — the Golden Point stated rather than weighted, throughout the cone. If it is resolved, the requirements are settled; if they are settled, there is a fact about whether any given contribution is among them. So either that fact is available, in which case the fences fail and the complacency inference goes through — or it is not available even in the resolved case, and one wonders what "resolved" was supposed to mean. Push the first horn and the Route World undermines the conduct it recommends; push the second and it looks like a hypothesis with no content. Either way, so the objection concludes, the Route World is incoherent and its incoherence is a proof that we are not in one.

The answer, and it is not a concession. The objection equivocates on "available." Statedness is a property of an *Aethus*, of what the world's books carry, and the framework is explicit that

an Aethus is deductively closed and indexed without regard to whether its bearer can compute over it [5]. So in a Route World the requirements are determinate *in the books* and remain inaccessible *to the reasoner*, and no contradiction arises, because those are different predicates of different objects. What Theorem 3.6 forbids is not there being a fact but *certification of it from observation*: Q and $\mathbb{P}$ are mutually absolutely continuous on every finite window, so no finite record distinguishes them. That is a limit on inference and not on determinacy.

Two corrections the objection earns. First, the fences should not have said *in principle*, and above they no longer do: the measures are singular on the infinite-horizon σ-algebra, so an observer of unbounded duration would distinguish them, and what the ceiling supplies is unavailability to any *finite* observer. Second, the resolved case is not contentless. What "resolved" means is the technoanatomy companion [3]'s distinction, one is under the measure Q rather than the family $\mathbb{P}^{(t)}$, and that has consequences the section spends its length on, including the evidence flux that orders the three worlds. A hypothesis can be substantive and its truth still uncertifiable; this work's own epistemic ceiling is the standing example, and it applies to this work's conclusions as firmly as to its targets.

And the structure is one the section already carries. Remark 7.19 makes the same distinction on the evidential side: the attribution information is discarded *at the projection*, not in the world, so which events supplied the accumulated evidence is determinate and not recoverable. Determinate-and-inaccessible is the framework's normal condition rather than a special pleading introduced to save the fences. *And a route that closes the leverage without the diagnosis.* Even were the objector granted the availability premise arguendo, no model comparison against the Route World follows, for a structural reason independent of the equivocation above: the ceiling is a property of the model under every hypothesis of §7.4, Void, Weak, and Strong alike, so a premise that falsifies all three worlds at once selects among none of them. What an exhibited certification would refute is the mutual-absolute-continuity structure itself, at the site where its empirical exposure lives (the survivorship companion [2]), and the Route World would stand or fall with its rivals rather than before them.

Remark 9.2 (The robustness argument, and why it is not relied on). A stronger conclusion suggests itself and should be marked as the weakest thing here. If each conservative alternative, conditioning on some nearer, more peripheral future event rather than on the Golden Point, is one whose own passage will dissolve whatever objectivity it seemed to have, then only a target at the asymptote remains stable under the motion the argument itself describes; and one may be tempted to conclude that nothing *but* the Golden Point can be coherently conditioned on.

Two reasons not to lean on it. It requires that the peripheral alternatives be exhaustively surveyable, which is the same exhaustiveness the companion's own arguments purchase carefully and this one assumes. And it is the argument's only step that is not a likelihood computation, so a reader who accepts (14) and Theorem 3.2 and rejects this paragraph loses nothing else. The accumulation is what gives the Route World teeth; the robustness claim is a conjecture stated beside it **[O]**.

Remark 9.3 (What the Route World does not license). One reading has to be closed explicitly, because it is the natural one and it is dangerous. If required flukes occur, then, the reading goes, an individual contemplating some improbable feat should ask not whether they will succeed but whether the Golden Point requires their succeeding, and proceed accordingly. Nothing in this work supports that, and two of its results forbid it. By the broader Golden program, set aside here an individual is not a lever on their biosphere's hazard: what they hold is a position, not a purchase, and Golden Optimation is a statement about which histories one finds oneself in

rather than about what any agent can bring about. And by Theorem 3.6 nobody can determine whether their own feat is among the requirements, since no finite observation places a system on the interpolation at all. The premise of the reading is therefore unavailable to any finite observer, which is not the same as there being no fact of the matter (Remark 9.1).

What survives is weaker and is the defensible form: a Route World is one in which improbabilities are more common than the Cosmic Nexus's rates predict. It is not one in which any particular improbability is owed to any particular person, and an agent who acts on the stronger reading is not applying this framework but discarding Theorem 3.6. the broader Golden program, set aside here fences the neighboring case in the same terms and for the same reason.

The phenomenology extended: from events to constitution. The Route World as developed in this section is a claim about *events*: which occurrences carry weight, how the record reads under the conditioning, what the forward flux does. Its Strong reading supports one further extension, developed where the categorical machinery lives rather than here: from the structure of events to the constitution of things — the universe's contents as weight-carrying excursions on the Aethus that states the conditioning attribute (Definition 7.3). Nothing about the Route World's own claims strengthens or weakens by the extension, and its fences govern there unweakened; the pointer is recorded here because a reader of this section should know the hypothesis's full reach before weighing it.

Remark 9.4 (A consequence for periodization). One application is worth recording because it is where the Route World meets Principle 1 and returns something concrete. Golden Optimation running over the ancestral record and over the present is one process under one conditioning, so there is no categorical transition between the environments of natural history and those of the present — which is continuity's own claim, arrived at from the conditioning side. The present is nonetheless distinguished in *stakes*, by the broader Golden program, set aside here, and the two are compatible for the reason the broader Golden program, set aside here gives: a monotone sequence distinguishes every later point over every earlier one without distinguishing any point categorically. The right image is a field potential that is high here because the Golden Point is near ahead — and the misreading to guard against is that a high potential marks a step. It does not: a potential rises continuously toward its source, and what is high at the present is high because of proximity to a transition that lies ahead, not because a transition has been crossed.

The consequence for periodization is that a boundary drawn in the past, an Anthropocene, on any of its proposed placements, marks a change in stakes rather than in kind, and continuity is what denies it the second reading. The argument should be run from the principle and not from the failure to locate a line, since inability to place a boundary is a sorites and not a proof. What the Route World adds is a positive alternative: the transition the periodization is reaching for lies *ahead*, at the Golden Point, which is the one place the framework does mark a change in kind — and which Theorem 3.6 forbids anyone from dating.

9.2 What this section does not claim

The fence is stated hard, on the companion's discipline that an apparatus which prices what it claims must also refuse what it does not [8]. It is not claimed that any observed system is Golden, ideally or practically; by Theorem 3.6 the ideal version is unknowable to any finite observer (the technoanatomy companion [3]) and the practical version is out of reach for want of an ensemble. It is not claimed that the companion's cosmic weighting and the path measure

$\mathbb{P}$ of Section 3 are the same object; that identification is flagged as unperformed in the technoanatomy companion [3] and nothing here depends on it. It is not claimed that any individual biosphere, ours included, will behave as the technoanatomy companion [3] describes; those are statements about a conditional distribution. No normative conclusion is claimed ($\Phi 2$). It is not claimed that the Golden Axiom holds: it is stated at **[O]**, and the author's argument for it, the Paradox of Departures (Section 8), is recorded at **[S]** and certified by nothing (Theorem 3.6). And the companion's natural-historical program, its conjectures, its bounds, its paleontological predictions, is not claimed, imported, or re-argued; $\Phi 5$ enters as a stated result and nowhere else.

One thing remains on the far side of the fence, because a fence is legible only if what it excludes can be seen. A program built on this section would inherit three commitments, stated here as refusable rather than as claims. It would be committed to the boundary-cost scaling of $\Phi 3$ showing up in institutional and ecological data, not merely in argument. It would be committed to the truncation/rescaling asymmetry appearing in survivorship-selected populations generally. And it would be committed to the exponent's dependence on noise placement, $\frac{1}{4}$ for integrated drivers, $\frac{1}{2}$ for Brownian ones, being visible in any domain where hazard dynamics can be measured directly. None of the three is established here, all three could be found false without touching a line of Section 3, and that is the point of naming them.

10 The prospective test

This section is a protocol template and is called one throughout: a declared test needs actual observables, numerical predictive distributions under both hypotheses, an observation interval, a scoring rule and a stopping rule, and the template below supplies the form of each without yet supplying the numbers; until it does, the section specifies a test to be declared, not a test declared.

The Route World's flagship empirical discriminator is not any of the retrospective cases above, which are labeled exploratory where they appear, but a test declared before its observation interval. The imported theorem does not enforce prospective target selection; the retrospective-target objection is answered only by a declared scan, which fixes the target, the attribute family and each attribute's alternative before the record is read, and nothing short of that closes it. The test is therefore declared here, in the form the theorem companion prescribes. The target family is survival to horizon t of the biosphere, read through the Golden target of Section 4; the rival law is the observer-conditioned draw. The attribute family is the set of prerequisites the Golden target is argued to require and the observer target is insensitive to, fixed in number before scoring, with the dependence assumption stated as submultiplicativity or a bound on the conjunction. The baseline priors are the Cosmic-Nexus weights the natural-history leg's method estimates. The record statistic is the conjunction of those prerequisites observed over the interval, and the reported quantity is the Bayes factor between the conditioned and unconditioned laws. The stopping rule is a fixed interval, and the multiplicity budget is the expected number of spurious κ-fold flags at the declared κ. The provisioning test, which asks whether departure-relevant resources sit where the Golden target requires them at a rate above the habitability-conditioned base rate, is the same protocol at a second grain and awaits an exoplanet census. Until a test so declared has been scored, the Route World is a hypothesis with an estimated Bayes factor from retrospective material, and it is described that way.

11 Open problems

Every [O] tag in the paper is gathered here. The estimate of the natural-history leg's exponent α by a direct attribute-level audit of the record. The identification map from accordance-legible traces to the target's operation. The formal dissolution of the finale paradox at the grade of the draw. Strong Past-Alignment, conditional on the cumulative-suppression landscape assumption, which is the Optimal-Earth companion's and not this paper's. The landscape premise under which every alternative lineage is an Imperfection Magnitude Drop. The shifted convergence result on which any forward reading of practical Goldenness depends. The provisioning base rate. An explicit intermediate law for the Weak reading, a partial-conditioning family whose expected log-likelihood growth can be computed and ordered between the two rigorous signs. And the Route World itself, entered as a hypothesis: what is derived is its structure, what is open is whether the record is under it. The Golden Axiom, the strong reading stated in the framework's primitives, is open in the same way (Axiom 1); the author's argument that it holds is recorded at **[S]** in Section 8, and the external form's bound for a channel whose rate varies in time is open.

12 Falsifiers

What would count against the hypothesis, in one place. A Bayes factor between the conditioned and observer-conditioned laws, on a predeclared statistic, found near or below one. The information flux measured and found at the rate the unconditioned law predicts. What is nondecreasing against a fixed raw law is the relative entropy I_t; its derivative $\mathcal{J}_t$, the information flux, need not itself increase where it exists. Probability-zero continuations are not thereby impossible continuations: the critical conditioned process assigns weight to histories lying in a null set of the original law, and structural impossibility and measure-relative nullity are defined separately. The provisioning base rate found undistinguished from the habitability-conditioned one. A perturbation exhibited that leaves a Golden-relevant trait's Cosmic-Nexus weight undiminished, which weakens local alignment, and a systematic class of such perturbations, which breaks it. A route-deleting fluke whose complement is shown at least as Golden-productive, at a rate above the prior bound's p, or a stockpile whose members fail the route-deletion audit individually or whose family fails submultiplicativity. And a positive calibration in the natural-history leg that fails the once-only test. Against the Golden Axiom, the departure of one's own biosphere, a survival attribute failing at a finite proper time, which no member of the departed biosphere is placed to certify; and against the Paradox of Departures, an estimate of the record's Cosmic weight q near one, which leaves its general form's cap vacuous. Against the ceiling no falsifier is offered, because it is a theorem; what it forbids is reading any of these, unfired, as certification.

13 Conclusion

The claim stated at the outset is a hypothesis and stands as one. Under the stated counterfactual-weight and target-requirement assumptions, the record of natural history yields a Bayes factor favoring conditioning on the biosphere's indefinite survival over conditioning on the existence of observers, estimated from the record's technological-route prerequisites and bounded from its natural-historical counterfactual weight; the scientific burden now sits entirely in establishing the two probabilities independently of the record they are scored on, which is what the prospective

protocol is for, and until it has been run the factor is a retrospective estimate under assumptions and is described that way. Every consequence drawn from the hypothesis carries a test. The theorem that makes the hypothesis well posed, that a future-targeted draw leaves fingerprints on the past without acting on it, is the companion's, and this paper adds to it only the target, which it constructs, the arguments, which it states as comparisons, the instrument, which it reads as an instance, and the discriminators, which it names. It also states the strong reading once in the framework's primitives, as the Golden Axiom, and records the author's argument that it holds, the Paradox of Departures, at its grade. What the hypothesis cannot have is certification, by the theorem it rests on; what it can have is a Bayes factor and a declared test, and the posture that follows is the one the mathematics imposes: held, not possessed.

The theorem extraction; future-targeted accordance under the conditioned draw, the multiplicity guard, and the Bayes-factor reading. Imports only GoldenSurvivorship. 2026.

[2] Ajax Benander. *Survivorship Conditioning for Hazard Rates Driven at the Log-Derivative Level*. Working draft. The Golden branch's root extraction; the two-condition viability theorem with its piecewise driver-viability functional, the hard-wall and soft-wall conditioned laws, the certification ceiling, and the half-time theorem. 2026.

[3] Ajax Benander. *Technoanatomy: Civilizational Survival as a Sign, Not a Size*. Working draft. The mechanism extraction; the prerequisite schedule, the surviving-completion kernel, the survival-time threshold, and the front-loaded settlement result. 2026.

[4] Ajax Benander. "Nexic Reasoning: Defining a Generalized Calculus Over Anthropic Parameters". In: (Dec. 2024). DOI: 10.31219/osf.io/jvkcp. Alternative URL: osf.io/jvkcp. URL: https://philpapers.org/rec/BENNRD.

[5] Ajax Benander. "Aethic Reasoning: A Comprehensive Solution to the Quantum Measurement Problem". In: (Nov. 2024). Alternative URL: https://philsci-archive.pitt.edu/id/eprint/25713. URL: https://philpapers.org/rec/BENARA-5.

[6] Ajax Benander. *Golden Science*. Self-hosted manuscript. Title page August 2022, the date of the first version of the source; this version created November 2022. Not deposited to a preprint server; cited as a dated developmental record rather than as a source of results. Nov. 2022. URL: https://aethus.org/aethic-code/history/GoldenScience_Nov2022.pdf.

[7] Ajax Benander. *Newcomb's Problem Without a Fixed Past: A Decision Rule From Observer-Indexed Determinacy*. Preprint. The decision-theoretic face; settling-invariance on the joint law, binding modes, and the Egan equilibrium. 2026. URL: https://philpapers.org/rec/BENNPW.

[8] Ajax Benander. *The Optimal Earth: A Paradigmatic Re-Rendition of Natural History from Coupled Improbability*. Preprint. The natural-history extension; the conditional observer-mass concentration theorem and the Optimal-Earth Conjecture. 2026. URL: https://philpapers.org/rec/BENTOE-4.

[9] Ajax Benander. *The Weight Algebra of Aethae: A Two-Layer Commutative Semiring for Superposition and Pruning*. Preprint. The algebraic support extraction; owns the Aethus as a formal object, the refinement order, formal validity, and the two-layer algebra. 2026. URL: https://philpapers.org/rec/BENTWA-5.

[10] Ajax Benander. *Ajax's Math Ideas (grade-school idea journal)*. Self-hosted dated record. Dated entries from 2019 onward; the Golden Point's coinage, mid-January 2021, among them. 2021. URL: https://aethus.org/aethic-code/history/ajax-grade-school-ideas.html.
